ABSTRACT
A fully humanized antibody having binding specificity to Toll-like Receptor 2 comprises a light chain and a heavy chain entirely comprised of amino acid sequence of human origin. The variable region of the light chain comprises an amino acid sequence which is substantially homologous with the sequence of SEQ ID NO:1, while the variable region of the heavy domain comprises an amino acid sequence which is substantially homologous with the sequence of SEQ ID NO:4. Also provided are nucleic acids encoding such antibodies, as well as the use of the antibodies in medicine, in particular for the treatment of inflammatory and autoimmune diseases which are mediated by Toll-like Receptor 2 activation and signalling.

HUMANISED ANTIBODIES TO TOLL-LIKE RECEPTOR 2 AND USES THEREOF

FIELD OF THE INVENTION

The present invention relates to fully humanised antibodies and fragments thereof, and in particular, to fully humanised antibodies which have binding specificity for Toll-like Receptor 2 (TLR2, TLR-2). The invention further extends to the use of said fully humanised antibodies for the treatment and prevention of inflammatory and autoimmune diseases mediated by Toll-like Receptor 2 activation and signalling.

BACKGROUND TO THE INVENTION

Toll-like Receptors (TLRs) form a family of pattern recognition receptors which have a key role in modulating the innate immune response, they are also involved in tissue repair, maintenance of tissue integrity and tumorigenesis. Eleven Toll-like Receptors have been identified in humans to date. The members of the Toll-like Receptor family are highly conserved, with most mammalian species having varying 10 to 15 Toll-like Receptors. Each Toll-like Receptor recognises specific pathogen-associated molecular signatures. Toll-like Receptor 2 (TLR2, CD282, TLR-2) can be activated by pep- tidoglycan, lipoproteins, lipoteichoic acid and endogenous ligands.

A number of monoclonal antibodies which have binding specificity for Toll-like Receptor 2 are known. WO 01/36488 discloses an antibody, designated as TL2.1, which is derived from a hybridoma cell line deposited in accordance with the Budapest Treaty at the European Collection of Cell Cultures (ECACC) under the accession number 99102832. This antibody antagonises the activation of Toll-like Receptor 2 expressed on human cells.

WO 2005/028509 discloses a murine monoclonal antibody, designated T2.5, which specifically inhibits the activation of mammalian TLR2. The T2.5 monoclonal antibody is shown to be cross-reactive to both human and murine forms of TLR2. This document further contains experimental data which suggests that the murine T2.1 anti-TLR2 monoclonal antibody, as disclosed in WO 01/36488, is not cross-reactive to both human and murine forms of TLR2, as was stated in the description of that patent application. Rather, the T2.1 antibody is shown in WO 2005/028509 as only binding to human Toll-like Receptor 2 and not murine Toll-like Receptor 2. The T2.5 monoclonal antibody of WO 2005/028509 was raised against the extracellular domain of TLR2, and therefore has binding specificity to an epitope in that area of Toll-like Receptor 2.

WO 2005/019431 discloses an antibody which has binding specificity to TLR2, which is designated 11G7. This murine antibody can be derived from hybridoma cell line 11G7 as deposited with the American Type Culture Centre (ATCC) under the designation PTA-5014. The 11G7 monoclonal antibody selectively binds to the extracellular domain of TLR2 and can block the induction of cytokine production by human peripheral blood mononuclear cells (PBMCs) stimulated with an agonist which activates a heterodimer formed between Toll-like Receptor 1 (TLR1) and TLR2. The 11G7 antibody does not inhibit cytokine production by PBMCs stimulated with an agonist which induces signalling through a heterodimer formed between Toll-like Receptor 6 (TLR6) and TLR2.

The use of rodent monoclonal antibodies, such as murine monoclonal antibodies, for in-vivo therapeutic applications has been shown to be associated with the generation of undesirable immune responses which are generated by the subject to whom the antibody is administered. Such immune responses can result in the production of antibodies which effectively neutralise the effectiveness of the therapeutic antibody. Such immune responses are typically referred to as human anti-mouse antibody (HAMA) responses. HAMA responses compromise the therapeutic effectiveness of the administered antibody in a number of ways, including impeding the ability of the therapeutic antibody to reach its binding target, this compromising the therapeutic effect of the antibody.

A number of approaches have been developed to address the issue of unwanted HAMA responses being raised against therapeutic antibodies which are administered to individuals. Typically, these approaches involve techniques which result in the replacement of certain components of the mouse antibody with equivalent portions derived from a human antibody. Such approaches can, for example, result in the production of chimeric antibodies which comprise murine variable regions joined to human-derived constant regions. Alternatively, a technique known as “CDR grafting” can be employed, wherein the complementarity determining regions (CDRs) from a murine antibody are grafted into a framework provided by regions of human antibody light and heavy chain variable domains. This results in the production of an antibody which retains the binding specificity of the murine antibody, but where the only non-human components are the grafted murine CDRs regions.

However, in both of these approaches, the therapeutic effectiveness of the resulting humanised antibody can be impaired. For example, the murine variable region component of a chimeric antibody can still provide the basis for a HAMA response to be mounted there against. Further, where CDR grafted humanised antibodies are produced, it has been observed that simple transplantation of the CDR regions often results in a reduced therapeutic efficacy of the antibody due to the binding affinity of the antibody being diminished.

The inventor has therefore identified the need to generate fully humanised monoclonal antibodies which have binding specificity for Toll-like Receptor 2, and which antagonise TLR2 function, but which are essentially non-immunogenic in humans. Following extensive experimentation, the inventor has produced a fully humanised monoclonal antibody which have binding specificity to human Toll-like Receptor 2, and which antagonises TLR2 function irrespective of whether Toll-like Receptor 2 forms a heterodimer with Toll-like Receptor 1 or Toll-like Receptor 6. This TLR2 antagonistic antibody is not produced from previously known chimeric or CDR-grafting techniques and therefore does not contain any murine amino acid residues. Furthermore, the antibody is shown to mediate TLR2 neutralisation without the need to bind to the CD32 cell surface antigen, this being a functional requirement of other known Toll-like Receptor 2 antagonistic antibodies. Furthermore, the fully humanised antibody of the invention is the first fully human TLR2 neutralising antibody to be known in the art. The antibody does not exhibit any T cell epitopes and therefore neutralising antibodies are not raised there against when administered to a subject. The anti-TLR2 antagonistic antibodies further exhibit a broad level of cross-reactivity to Toll-like Receptor 2 as expressed by a wide
range of mammalian cells, with binding of the fully humanised antibody being surprisingly observed to bind to Toll-like Receptor 2 expressed on human, mouse and monkey cells.

SUMMARY OF THE INVENTION

According to a first aspect of the invention there is provided a neutralising antibody, or an antigen binding portion thereof, which is capable of specifically binding to Toll-like Receptor 2 (TLR2, CD282, TLR-2), and wherein the antibody or antigen binding portion comprises, consists or consists essentially of a light chain and a heavy chain wherein the variable region of the light chain (VL) comprises an amino acid sequence which is identical or substantially homologous to the amino acid sequence of SEQ ID NO:1, and wherein the variable region of the heavy chain (VH) comprises, consists or consists essentially of an amino acid sequence which is identical or substantially homologous to the amino acid sequence of SEQ ID NO:4.

As defined herein, the term neutralising antibody describes an antibody that is capable of neutralising the biological activity and signalling of Toll-like Receptor 2. The neutralising antibody, which may also be referred to as an antagonistic antibody, or a blocking antibody, specifically and preferentially selectively, binds to Toll-like Receptor 2 and inhibits one or more biological activities of Toll-like Receptor 2. For example, the neutralising antibody may inhibit the binding of a ligand or substrate, such as a Toll-like Receptor 2 ligand, to the Toll-like Receptor 2 ligand binding site. Alternatively, the neutralising antibody may prevent the activation of Toll-like Receptor 2 once bound by a ligand agonist, for example by impairing ligand agonist binding. Typically the neutralising antibody selectively binds Toll-like Receptor 2 and, therefore, does not substantially bind other Toll-like Receptor family members (e.g., Toll-like Receptor 4) under physiological or therapeutic conditions.

In certain embodiments, the Toll-like Receptor 2 neutralising antibody mediates antagonism of Toll-like Receptor 2 functional activity independently of the requirement of the anti-Toll-like Receptor 2 antibody, or binding fragment, to bind to CD32 (Fc gamma receptor II (FcγRII, FcgRII), in particular CD32a and/or CD32b. Accordingly, the neutralisation of Toll-like Receptor 2 does not require binding of the antibody, and in particular the Fc portion of the antibody, or antibody fragment, to CD32.

Typically the anti-Toll-like Receptor 2 antibodies of the invention are characterised in that they do not contain any binding epitopes against which an immune response can be mediated when the antibody is administered to a subject, in particular a human. Such a characteristic is important in preventing the generation of neutralising antibodies against the antibodies of the invention in the subject to whom the antibodies are administered, as the therapeutic efficacy of the antibodies can be severely impaired should such an immune response occur.

Typically, the neutralising anti-Toll-like Receptor 2 antibody is a fully humanised antibody. That is, all the combinations of amino acid residues which comprise the antibody are entirely of human origin, and do not therefore contain, for example, human and non-human regions. In particular, the antibody of the invention comprises human variable region sequences only. The antibody of the invention therefore differs from, for example, a chimeric monoclonal antibody which consists of amino acid residues derived from both mice and humans at the variable regions of the heavy and light chains, or from a CDR-grafted “humanised” antibody, where the complementarity determining regions (CDRs) of the heavy and light chain variable regions comprise amino acid residues derived from a murine antibody, while the associated framework regions (FR) of the antibody and the constant regions (CR) are derived from a human antibody. Hence, the fully humanised antibody of the invention has variable and constant regions, of both the heavy and light chains, which are all of human origin, or which are substantially identical to sequences of human origin, albeit not necessarily from the same antibody. The fully humanised antibodies of the invention may be further referred to as “humanised” antibodies, or as an antibody derived fully from human sequences.

The amino acid sequence of the variable region of the light chain (VL) of the antibody of the invention is shown below as SEQ ID NO:1:

```
DILVTQSPATLSSLPGERATLSCRASSEVEYGGTSLSMQYQQPQPPKLYLPGASESNGVSPERPSGSQSGTDPFTKISRVEAEVVMFPCQGSRKLPW
```

In SEQ ID NO:1, as shown in FIG. 1, the underlined residues relate to the location of complementarity determining regions, wherein residues 24 to 34 relate to CDR1, residues 50 to 56 relate to CDR2 and residues 89 to 97 relate to CDR3. FIG. 1B shows the variable light chain nucleotide sequence and the deduced amino acid sequence. In this figure, the residues of the light chain domain are conventionally numbered according to the Kabat numbering system (Kabat E A et al., (1991) Sequences of proteins of immunological interest, 5th edition. Bethesda: US Department of Health and Human Services).

It should be noted that the identification of these CDR residues is consistent with the residues assigned to the CDR regions using the Kabat numbering system, wherein VL.CDR1 (i.e. complementarity determining region 1 of the light chain variable domain) comprises residues 24 to 34, VL.CDR2 (complementarity determining region 1 of the light chain variable domain) comprises residues 50 to 56 and VL.CDR3 (complementarity determining region 1 of the light chain variable domain) comprises residues 89 to 97.

As herein defined, an amino acid sequence which is substantially homologous to the amino acid sequence of SEQ ID NO:1 means an amino acid sequence which has at least 90% amino acid sequence identity, more preferably 95% sequence identity, and most preferably at least 98% amino acid identity over a length of at least 20, 50 or 100 amino acids, or of the entire sequence length, to the amino acid sequence of SEQ ID NO:1. Typically such homologous amino acid sequences will have binding specificity for Toll-like Receptor 2 and, when bound to Toll-like Receptor 2, will antagonise Toll-like Receptor 2 functional activity.

Typically, the variable region of the light chain (VL) is joined to a human immunoglobulin Kappa constant domain (CL) to provide a light chain, said light chain being the light chain of the humanised antibody.

Accordingly, in certain embodiments, where the antibody or binding member of the invention comprises a complete light chain, the light chain has the amino acid sequence of SEQ ID NO:2:

```
DILVTQSPATLSSLPGERATLSCRASSEVEYGGTSLSMQYQQPQPPKLYLPGASESNGVSPERPSGSQSGTDPFTKISRVEAEVVMFPCQGSRKLPW
```

```

```
LPGASNVESGVPSREPSGSQSGTDPFTKISRVEAEVVMFPCQGSRKLPW
```

```
TPQQGKVEIRTVAAPSVPSVFPEDQELKGSATSVVLCLSNFYPREKCLQ
```
In certain further embodiments, the invention extends to an antibody or binding member comprising a light chain which comprises, consists or consists essentially of an amino acid sequence having an identity of at least 80%, more preferably at least 90%, more preferably at least 95% and most preferably 98% identity to the amino acid sequence of SEQ ID NO:2. Typically the antibody which comprises the amino acid sequence which has at least 80% or greater amino acid identity with SEQ ID NO:2 will specifically bind to Toll-like Receptor 2 and when bound thereto, will serve to antagonise Toll-like Receptor 2 functional activity.

In certain embodiments, the amino acid sequence of the light chain, as defined in SEQ ID NO:2 and as depicted in FIG. 3, is encoded from the nucleotide sequence of SEQ ID NO:3 as shown in FIG. 4. In the sequence of SEQ ID NO:3 shown in FIG. 4, the underlined nucleic acids encode the amino acids of the light chain variable region.

In one embodiment, the amino acid sequence of the variable region of the heavy chain (VH) is shown below as SEQ ID NO:4:

```
QVQLVQSGSELEKPGASVKLCKASQGRFTDGYGINVRGAPQPSLEWIGW
```

```
YPQEGSTNSFFENFDKATTVTDASTAYNELSSLQRRDDTAYFCALT
```

```
GSGTFLDVGWGQTIVTVS
```

In SEQ ID NO:4 as shown in FIG. 2, the underlined residues relate to the amino acid residues of the 3 complementarity determining regions, wherein residues 31 to 35 relate to CDR1 (VHCDR1) (complementarity determining region 1 of the heavy chain variable domain)), residues 50 to 65 relate to CDR2 (VHCDR2) and residues 95 to 103 relate to CDR3 (VHCDR3). It should be noted that the positioning of these CDR residues differs slightly to the positioning typically ascribed to the CDR regions using the Kabat numbering system, wherein CDR1 is present at residues 31 to 35, CDR2 is present at residues 50 to 66, and CDR3 is present at residues 95 to 103.

As herein defined, an amino acid sequence which is substantially homologous to the amino acid sequence of SEQ ID NO:4 means an amino acid sequence which has at least 90% amino acid sequence identity, more preferably 95% sequence identity, and most preferably at least 98% amino acid sequence identity over a length of at least 20, 50 or 100 amino acids of the amino acid sequence of SEQ ID NO:4. In certain further embodiments, the invention extends to an antibody or binding member comprising a heavy chain variable (VH) domain which comprises, consists or consists essentially of an amino acid sequence homology of at least 80%, more preferably at least 90%, more preferably at least 95% and most preferably 98% sequence identity to the amino acid sequence of SEQ ID NO:4.

Typically, the variable region of the heavy chain (VH) is conjugated to a further amino acid sequence which comprises at least one immunoglobulin constant domain. In certain embodiments, the immunoglobulin constant domain is derived from an antibody of the subclass IgG (immunoglobulin G) to form the complete heavy chain of the humanised antibody of the invention. Accordingly, said constant domain may comprise CH1, CH2 and CH3 along with a suitable linker located between said CH1 and CH2 domains.

In certain further embodiments, the发明 extends to an antibody or binding member comprising a heavy chain which comprises a homologous amino acid sequence having an amino acid sequence identity of at least 80%, more preferably at least 90%, more preferably at least 95% and most preferably 98% to the amino acid sequence of SEQ ID NO:5.

In certain embodiments, the amino acid sequence of the heavy chain, as defined in SEQ ID NO:5 and as depicted in FIG. 5, is encoded from the nucleotide sequence of SEQ ID
NO.6 as shown in FIG. 6. In the sequence of SEQ ID NO.5 as shown in FIG. 5, the residues in bold are the hinge region, the residues in italics are the residues of the CH1 constant domain, the underlined residues are the residues of the CH2 constant domain and the residues listed after the underlined residues are the residues of the CH3 constant domain. In certain embodiments, the CH1, CH2 and/or CH3 constant domains may be substituted, in whole, or in part with a CH1, CH2 or CH3 domain derived from any suitable immunoglobulin subtype, such as, but not limited to IgG1, IgG2, IgA, or IgM. In certain embodiments, the deletion, addition or substitution of at least one amino acid residue present in any of the constant domains, may also be provided. Typically said deletions, additions or substitutions cause a resulting functional change in the binding properties of the Fe portion of the antibody, or antibody fragment, and in particular a modulation of the ability of the Fe region of the antibody to bind to Fc receptor and mediate effector functions.

In certain further embodiments, the present invention extends to an isolated antibody comprising a light chain variable domain of SEQ ID NO.1, or a variant which has at least 90% amino acid sequence identity thereto, and a heavy chain variable domain of SEQ ID NO.4, or a variant which has at least 90% amino acid sequence homology identity thereto.

In certain further embodiments, there is provided an antibody formed of a light chain comprising the amino sequence of SEQ ID NO.2, or a variant having at least 90% sequence identity thereto, and a heavy chain having the amino acid sequence on SEQ ID NO.5, or a variant which has at least 90% amino acid sequence identity thereto.

It will be appreciated that the variable and constant domains of both the light and heavy chains for use in producing the antibodies and antibody fragments of the present invention, may include variants of these domains, for example, said variable and constant domains may comprise one or more amino acid variations compared to the sequence of these domains as described herein. It will be appreciated that the constant domains may be longer or shorter than the constant domains described herein. In certain embodiments, the variant variable or constant domains may have a sequence homology of at least 90% identity or similarity to a wild type antibody constant domain.

As herein defined “sequence homology” may also be referred to as sequence identity or sequence similarity. The term “identity” or “sequence identity” as used herein, means that at any particular position in the aligned sequence, the amino acid residue is identical between the aligned sequences. The term “similarity” or “sequence similarity” as used herein, indicates that, at any particular position in the aligned sequences, the amino acid residue is of a similar type between the sequences. For example, leucine may be substituted for an isoleucine or valine residue. This may be referred to as conservative substitution. Preferably when the amino acid sequences of the invention are modified by way of conservative substitution of any of the amino acid residues contained therein, these changes have no effect on the binding specificity or functional activity of the resulting antibody when compared to the unmodified antibody.

Sequence homology, or sequence identity with respect to a (native) polypeptide of the invention and its functional derivative relates to the percentage of amino acid residues in the candidate sequence which are identical with the residues of the corresponding native polypeptide, after aligning the sequences and introducing gaps, if necessary, to achieve the maximum percentage homology, and not considering any conservative substitutions as part of the sequence identity. Neither N- or C-terminal extensions, nor insertions shall be construed as reducing sequence identity or homology. Methods and computer programs for performing an alignment of two or more amino acid sequences and determining their sequence identity or homology are well known to the person skilled in the art. For example, the percentage of identity or similarity of 2 amino acid sequences can be readily calculated using algorithms e.g. BLAST (Altschul et al. 1990), FASTA (Pearson & Lipman 1988), or the Smith-Waterman algorithm (Smith & Waterman 1981).

In a further aspect, the present invention provides a fully humanised antibody which has binding specificity for the epitope present on Toll-like Receptor 2, which is recognised by the murine monoclonal antibody T2.5, wherein said human antibody comprises:

- a light chain variable wherein the variable region comprises, consists or consists essentially of the amino acid sequence of SEQ ID NO.1,
- a heavy chain wherein the variable domain comprises, consists or consists essentially of the amino acid sequence of SEQ ID NO.4,
- or a variant which has at least 90% amino acid sequence identity thereto.

In certain embodiments, the antibody may be conjugated to at least one effector or reporter molecule.

In certain further aspects, the present invention extends to a fully humanised monoclonal antibody, designated OPN-305, which comprises a light chain variable region having the amino acid sequence of SEQ ID NO.1 and a heavy chain variable domain having the amino acid sequence of SEQ ID NO.4. The OPN-305 antibody may be further defined as having a light chain consisting of, or consisting essentially of the amino acid sequence of SEQ ID NO.2 and a heavy chain consisting of, or consisting essentially of the amino acid sequence of SEQ ID NO.5.

The term “consists essentially of” or “consisting essentially of” as used herein means that a polypeptide may have additional features or elements beyond those described provided that such additional features or elements do not materially affect the ability of the antibody or antibody fragment to have binding specificity to Toll-like Receptor 2. That is, the antibody or antibody fragments comprising the polypeptides may have additional features or elements that do not interfere with the ability of the antibody or antibody fragments to bind to Toll-like Receptor 2 and antagonise Toll-like Receptor 2 functional activity, such as modifications introduced into the amino acid sequence in order to reduce the immunogenicity of the antibody. For example, a polypeptide consisting essentially of a specified sequence may contain one, two, three, four, five or more additional amino acids, at either end or at both ends of the sequence provided that the additional amino acids do not interfere with, inhibit, block or interrupt the role of the polypeptide in an antibody or antibody fragment. Similarly, a polypeptide molecule which contributes to the Toll-like Receptor 2 antagonistic antibodies of the invention may be chemically modified with one or more functional groups provided that such functional groups do not interfere with the ability of the antibody or antibody fragment to bind to Toll-like Receptor 2 and antagonise its function.

In certain further aspects, the present invention extends to an isolated, fully humanised, monoclonal antibody, which comprises a light chain variable region comprising, consisting or consisting essentially of the amino acid sequence of SEQ ID NO.1 and/or a heavy chain variable domain having the amino acid sequence of SEQ ID NO.4.

As defined herein a “fully humanised” antibody refers to an antibody having variable regions in which framework regions (FR), constant regions (CR) and the complementarity-determining regions (CDR) are derived from human germline immunoglobulin sequences. Furthermore, if the antibody...
contains constant regions, then these constant regions are also derived from human germline immunoglobulin sequences. The fully humanised antibodies of the invention may include amino acid residues not encoded by human immunoglobulin sequences, such as mutations introduced by random, or site-specific mutagenesis in-vitro. However, a fully humanised antibody is not intended to include antibodies in which CDR sequences derived from the germline of other mammalian species, such as mice, have been grafted onto human framework sequences. A fully humanised monoclonal antibody is an antibody which displays a single binding specificity and which has variable regions in which both framework and CDR regions are derived from human germline immunoglobulin sequences. This differs from, for example, a humanised monoclonal antibody, where CDR sequences derived from the germline of another mammalian species, such as a mouse, have been grafted onto human framework sequences.

In embodiments where only the amino acid sequence of the variable heavy (VH) or variable light (VL) sequence are provided, then the invention extends to methods for producing antibodies which bind to the extracellular domain of Toll-like Receptor 2, in particular, mammalian Toll-like Receptor 2, typically human Toll-like Receptor 2, wherein said antibodies function to antagonise Toll-like Receptor 2 function, by screening said variable domain sequences against a library of complimentary variable domain sequences according to the teachings of Portolano et al. (Portolano et al. The Journal of Immunology (1993). 150:880-887) and Clarkson et al. (Clarkson et al. Nature (1991) 352: 624-628).

In certain further embodiments, the present invention provides an isolated antibody that specifically binds to human Toll-like Receptor 2, said antibody comprising a heavy chain variable domain comprising, consisting, or consisting essentially of the amino acid sequence of SEQ ID NO:4 and a light chain variable domain comprising, consisting or consisting essentially of the amino acid acid of SEQ ID NO:1. In certain embodiments, the isolated antibody is a substantially pure, isolated antibody that is substantially free of other antibodies having different antigenic specificities. In certain further embodiments, the antibody is a recombinant antibody, that is, that the antibody has been made by recombinant methods.

In certain further aspects, there is provided an antibody which specifically binds to Toll-like Receptor 2, wherein the antibody consists, or consists essentially of a light chain having the amino acid sequence of SEQ ID NO:2 and a heavy chain having the amino acid sequence of SEQ ID NO:5, wherein the antibody is cross-reactive (that is, that it has binding specificity) to Toll-like Receptor 2 expressed on human, murine and monkey cells. Typically the antibody binds to Toll-like Receptor 2 at a ligand binding site which, when bound by the antibody, prevents the activation of Toll-like Receptor 2 by a ligand agonist binding to the ligand binding site of Toll-like Receptor 2.

In various further aspects, the present invention extends to a multivalent monospecific antigen binding protein comprising two, three, four or more of the antibodies as defined in the foregoing aspects of the invention, or to fragments thereof, wherein said antibodies are bound to each other by a connecting structure.

In various further aspects, the present invention extends to binding members or antigen binding fragments derived from the fully humanised antibodies of the foregoing aspects of the invention. Such antigen binding fragments refer to one or more fragments of an antibody that retain the ability to specifically bind to an antigen, typically Toll-like Receptor 2. It has been shown that the antigen binding function of an antibody can be performed by fragments of a full length antibody. In certain embodiments, the binding members or antigen binding fragments may be isolated binding members. A binding member or antigen binding fragment of the invention may comprise a fragment of the antibodies of the present invention, e.g. a fragment of a fully humanised antibody molecule, such as the heavy or light chain only, or, for example, the variable domain of the heavy and/or light chain. In certain embodiments, a binding member may typically comprise, consist, or consist essentially of an antibody VH and/or VL domain. VH domains of binding members are also provided as part of the invention. Within each of the VH and VL domains are 3 complementarity determining regions ("CDRs"), along with 4 associated framework regions ("FRs"). A VH domain typically comprises 3 HCDRs (heavy chain complementarity determining regions), and a VL domain typically comprises 3 LCDRs (light chain complementarity regions). Accordingly, a binding member may comprise a VH domain comprising, in sequence, VH CDR1 (or HCDR1), CDR2 (HCDR2) and CDR3 (HCDR3) regions along with a plurality of associated framework regions. A binding member may additionally or alternatively comprise a VL domain comprising VL CDR1, CDR2 and CDR3 domains along with associated framework regions. The VH or VL domains typically comprise four framework regions, FR1, FR2, FR3 and FR4, interspersed between the 3 complementarity determining regions in the following arrangement: FR1-CDR1-FR2-CDR2-CDR3-CDR4-FR4.

The variable region of the light chain (VL) comprises 3 complementarity determining regions (CDRs) which have a role in conferring the binding specificity of the antibody, or binding fragment. The complementarity determining regions also may be known as hypervariable regions. The CDR complementarity determining regions are shown below as SEQ ID NO:7, SEQ ID NO:8, and SEQ ID NO:9, these relating to the VLCDR1, VLCDR2 and VLCDR3.

VLCDR1: (RASESVEYTVSTLYQG) (SEQ ID NO: 7)
Arg-Ala-Ser-Glu-Ser-Val-Glu-Tyr-Tyr-Gly-Thr-Ser-Leu-Met-Gln

VLCDR2: (GASNVES) (SEQ ID NO: 8)
Gly-Ala-Ser-Asn-Val-Glu-Ser

VLCDR3: (QSORKLWT) (SEQ ID NO: 9)
Gln-Gln-Ser-Arg-Lys-Leu-Pro-Trp-Thr

FIG. 1A shows the amino acid sequence of the VL domain of an antibody of the present invention as depicted in SEQ ID NO:1. FIG. 1B shows the variable light chain nucleotide sequence and the deduced amino acid sequence. The location of the VLCDR1, VLCDR2, and VLCDR3 regions is shown by the underlining of the appropriate amino acid residues which comprise each complementarity determining region (CDR) region in FIG. 1A.

In FIG. 1B, the residues of the light chain variable domain are conventionally numbered according to the numbering system devised by Kabat et al. (Kabat, E. A., Wu, T. T., Perry, H., Gottesman, K. and Foeller, C. (1991) Sequences of Proteins of Immunological Interest, Fifth Edition. NIH Publication No. 91-3242). The Kabat numbering system is generally used when referring to a residue in the variable domain (approximately residues 1-107 of the light chain and residues 1-113 of the heavy chain). This numbering system is used in the present specification except where otherwise stated. The
Kabat residue designations do not always correspond directly with the linear numbering of the amino acid residues of the heavy and light chain variable regions of the present invention. The actual linear amino acid sequence may contain fewer or additional amino acids than in the strict Kabat numbering corresponding to a shortening of, or insertion into, a structural component, whether a framework region or complementarity determining region (CDR), of the basic variable domain structure of the heavy or light chain. The correct Kabat numbering of residues may be determined for any given antibody by alignment of residues in the sequence of the antibody with a standard sequence to which the Kabat numbering has been applied.

VLCRD1 (also known as VL-CRD1, light chain variable domain complementarity determining region 1, or CDR-L1) consists of 15 amino acid residues present at residues 24 to 38 of the light chain variable domain sequence as shown in FIG. 1A. These residues are shown as residues 24 to 34 in FIG. 1B, where due account is taken of residues 27a, 27b, 27c and 27d. Hence, in the case of VLCRD1, 15 residues are taken to equate to CDR-L1 region defined according to Kabat.

VLCRD2 (also known as VL-CRD2, light chain variable domain complementarity determining region 2, or CDR-L2) as shown in FIG. 1A consists of 7 amino acid residues and is positioned from residues 50 to 56 of the variable domain sequence as shown in FIG. 1B. These residues correlate exactly with residues 50 to 56 as taken to equate to CDR-L2 region defined according to Kabat.

VLCRD3 (also known as VL-CRD3, light chain variable domain complementarity determining region 3, or CDR-L3) as shown in FIG. 1A consists of 9 amino acid residues and is positioned from residues 89 to 97 if the light chain variable domain sequence as shown in FIG. 1B. These residues correlate exactly with residues 89 to 97 as taken to equate to CDR-L3 region defined according to Kabat.

The variable region of the heavy chain (VH) also comprises 3 complementarity determining regions (CDRs) which have a role in conferring the binding specificity of the antibody or antibody fragment. The 3 complementarity determining regions are shown below as SEQ ID NO:10, SEQ ID NO:11, and SEQ ID NO:12, these relating to the VHCDR1, VHCDR2, and VHCDR3.

VHCDR1: 
(TVGIH (SEQ ID NO: 10))

VHCDR2: 
(NYFRDGEIYHTNREDH (SEQ ID NO: 11))

VHCDR3: 
(LTGGFPLDY (SEQ ID NO: 12))

FIG. 2A shows the amino acid sequence of the VH domain as depicted in SEQ ID NO:2. FIG. 2B shows the variable heavy chain nucleotide sequence and the deduced amino acid sequence.

In FIG. 2, the residues of the heavy chain variable domain are conventionally numbered according to a system devised by Kabat (supra). The location of the VHCDR1, VHCDR2, and VHCDR3 regions are shown by the underlining of the appropriate amino acid residues in FIG. 2A.

VHCDR1 (also known as VH-CRD1, heavy chain variable domain complementarity determining region 1, or CDR-H1) consists of 5 amino acid residues present at residues 31 to 35 of the variable domain sequence. These residues correlate exactly with residues 31 to 35 as taken to equate to CDR-H1 region defined according to Kabat.

VHCDR2 (also known as VH-CRD2, heavy chain variable domain complementarity determining region 2, or CDR-H2) consists of 17 amino acid residues and is positioned from residues 50 to 65 of the variable domain sequence. These residues correlate exactly with residues 50 to 65 as taken to equate to CDR-H2 region defined according to Kabat.

VHCDR3 (also known as VH-CRD3, heavy chain variable domain complementarity determining region 3, or CDR-H3) consists of 9 amino acid residues and is positioned from residues 95 to 103 if the light chain variable domain sequence. Due to the presence of 2 residues at position 100 and 100a, which are considered to align with residue 100 of the CDRH3 region of the Kabat derived CDRH3 region, as illustrated in FIG. 2R, these 9 residues correlate exactly with the 8 residues (residues 95 to 102) of the CDRH2 region defined according to Kabat.

The CDRs of the light chain associate with the CDRs of the heavy chain to confer the binding specificity of an antibody, or antibody binding fragment, in instances where both sets of CDRs are present. It is known that the contribution made by the light chain variable region to the energetics of binding is small relative to the associated heavy chain variable region. Accordingly, isolated heavy chain regions, which comprise, in sequence, the 3 complementarity determining regions (VHCDR1, VHCDR2, and VHCDR3), are known to have an antigen binding capability and are commonly referred to as single domain antibodies. Such antibody fragments are provided by the present invention, based on the provision of the heavy chain variable domain of the present invention, such as that defined in SEQ ID NO:1.

In various further aspects, the invention extends to a fully humanised antibody or related binding member which has binding specificity for Toll-like Receptor 2 (TLR2, TLR-2, CD282) and which comprises, consists or consists essentially of at least one amino acid sequence selected from the group comprising SEQ ID NO:7 to SEQ ID NO:12. In certain embodiments, the binding member comprises the amino acid sequences of SEQ ID NO:10, 11 and 12. In certain further embodiments, there is provided a binding member comprising, consisting or consisting essentially of, in sequence, the amino acid sequence of SEQ ID NO:10, SEQ ID NO:11 and SEQ ID NO:12. In certain embodiments, each of SEQ ID NO:10, SEQ ID NO:11 and SEQ ID NO:12 may be provided in sequence, with framework regions being interspersed there between.

In certain embodiments, the amino acid sequences of the VH or VL domains may comprise at least one back mutation, said back mutation being the replacement of an amino acid residue at a specific position of the sequence so as to improve the binding specificity of the humanised antibody or fragment thereof, to TLR2 and/or to enhance the therapeutic efficacy of the humanised antibody as a TLR2 antagonist. Typically such modification can be made to the framework residues within the light and heavy chain variable regions so as to decrease the immunogenicity of the antibody. In certain embodiments, further engineering techniques can be used to modify the antibodies of the present invention, for example by including modifications of the Fc region which can alter serum half-life, complement fixation, Fc receptor binding and/or antigen dependent cellular cytotoxicity. Further, in certain embodiments, the antibodies or antibody fragments can be produced which have altered glycosylation patterns. In certain embodiments, an antibody of the invention is altered to increase or decrease the extent to which the antibody is glycosylated.
Glycosylation of polypeptides is typically either N-linked or O-linked. N-linked refers to the attachment of a carbohydrate moiety to the side chain of a asparagine residue. The tripeptide sequences asparagine-X-serine and asparagine-X-threonine, where X is any amino acid except proline, are the recognition sequences for enzymatic attachment of the carbohydrate moiety to the asparagine side chain. Thus, the presence of either of these tripeptide sequences in a polypeptide creates a potential glycosylation site. O-linked glycosylation refers to the attachment of one of the sugars N-acetylglucosamine, galactose, or xylose to a hydroxylamino acid, most commonly serine or threonine, although 5-hydroxyproline or 5-hydroxlysine may also be used.

In certain further embodiments, the antibodies can be PEGylated by reacting the antibody with a polyethylene glycol (PEG) derivative. In certain embodiments, the antibody is defucosylated and therefore lacks fucose residues.

In certain embodiments, modifications in the biological properties of an antibody may be accomplished by selecting substitutions that affect (a) the structure of the backbone in the area of the substitution, for example, as a sheet or helical conformation, (b) the charge or hydrophobicity of the molecule at the target site, or (c) the bulk of the side chain. Amino acids may be grouped according to similarities in the properties of their side chains (in A. L. Lehninger, in Biochemistry, second ed., pp. 73-75, Worth Publishers, New York (1975)): (1) non-polar: Ala (A), Val (V), Leu (L), Ile (I), Pro (P), Phe (F), Trp (W), Met (M); (2) uncharged polar: Gly (G), Ser (S), Thr (T), Cys (C), Tyr (Y), Asn (N), Glu (Q); (3) acidic: Asp (D), Glu (E); (4) basic: Lys (K), Arg (R), His (H). Alternatively, naturally occurring residues may be divided into groups based on common side-chain properties: (1) hydrophobic: Norleucine, Met, Ala, Val, Leu, He; (2) neutral hydrophilic: Cys, Ser, Thr, Asn, Gin; (3) acidic: Asp, Glu; (4) basic: His, Lys, Arg; (5) residues that influence chain orientation: Gly, Pro; (6) aromatic: Trp, Tyr, Phe. Non-conservative substitutions will entail exchanging a member of one of these classes for another class. Such substituted residues also may be introduced into the conservative substitution sites or, into the remaining (e.g., non-conserved) sites.

In certain further aspects, the present invention extends to the use of the VL domain of SEQ ID NO:1, and/or the VH domain of SEQ ID NO:4 in the formation of a humanized antibody or a fragment thereof, where said antibody or fragment has binding specificity for Toll-like Receptor 2 and wherein said antibody or fragment functions to antagonise Toll-like Receptor 2 functional activity.

In certain further embodiments, the present invention extends to a binding member which has binding specificity to Toll-like Receptor 2 and which functions as a TLR2 antagonist, said binding member comprising, consisting of or consisting essentially of an amino acid sequence of SEQ ID NO:1 or SEQ ID NO:4 or to sequences which have an amino acid sequence homology of at least 80%, more preferably at least 90%, more preferably at least 95% and most preferably at least 98% thereto.

In certain further aspects, the invention extends to a fully humanised monoclonal antibody, designated OPN-305 which is characterised in the examples below. The light chains variable domain (VL) amino acid sequence of OPN-305 is shown in SEQ ID NO:1, while the heavy chain variable domain (VH) amino acid sequence of OPN-305 is shown in SEQ ID NO:4. Further, the heavy chain amino acid sequence of OPN-305 is shown in SEQ ID NO:5, while the light chain amino acid sequence of OPN-305 is shown in SEQ ID NO:2.

The antibody may be produced by recombinant means, such as cell culture, or alternatively the antibody may be an isolated antibody. In certain embodiments, further modifications may be made to the Fe portion of the heavy chain, and in particular to the CH2 and CH3 constant domains of the antibody. In such embodiments, the antibody will comprise a light chain having the amino acid sequence of SEQ ID NO:2 and the heavy chain variable domain comprising the amino acid sequence of SEQ ID NO:4. In other certain embodiments, a binding fragment may be derived from the OPN-305 fully humanised antibody, such as a Fab fragment, a Fab' fragment or an scFv.

In various further aspects, the present invention extends to an immunoconjugate comprising an antibody of this disclosure, or an antigen binding portion thereof linked to a partner molecule. In certain embodiments, such an antibody-partner molecule conjugate is conjugated by means of a chemical linker, such as a peptidyl linker, a hydrazine linker or a disulphide linker. In certain embodiments, the coupling partner is an effector molecule, label, drug, or carrier molecule. Suitable techniques for coupling the antibodies of the invention to both peptidyl and non-peptidyl coupling partners will be well known to persons skilled in the art. Examples of suitable labels include detectable labels, such as a radiolabel, or an enzymatic label, such as horse radish peroxidase, or chemical moieties, such as biotin. Alternatively, the label may be a functional label, for example, ricin, or pro-drugs which are capable of converting prodrugs into active drugs at the site of antibody binding.

In various further aspects, the invention extends to a bispecific molecule comprising an antibody or antigen binding portion thereof linked to a second functional moiety having a different binding specificity than said antibody or an antigen binding portion thereof.

In certain further aspects, the present invention extends to a monoclonal antibody; binding fragment derived from an antibody, a peptide, an oligonucleotide, a peptidomimetic or an organic compound which specifically binds to the same epitope present on the extracellular domain of Toll-like Receptor 2 as that bound by the monoclonal antibody OPN-305, wherein the monoclonal antibody is not the commercially available antibody designated T2.5. Typically the epitope which is specifically bound by the compound comprises the amino acid sequence of SEQ ID NO:13 and/or SEQ ID NO:14. Such compounds have the ability to cross-compete with the antibodies disclosed herein to bind to Toll-like Receptor 2 at the same epitope. Such compounds can be identified by means of cross-competition binding studies, which can be conducted against an antibody of the present invention, such as OPN-305.

In various further aspects, the present invention extends to the use of a fully humanised antibody, fully humanised monoclonal antibody or binding member derived therefrom according to the present invention in the prevention and/or treatment of a disease or condition which is mediated in totality or in part by Toll-like Receptor 2 activation and/or intracellular signalling.

In certain embodiments the TLR2-mediated disease or condition is an inflammatory condition.

In certain embodiments, the binding member may be selected from the group comprising, but not limited to; a Fab fragment, a Fab' fragment, a scFv (single chain variable fragment), a peptidomimetic, a diabody, or a related multivalent derivative.

Techniques used for the recombinant production of Fab, Fab' and F(ab')2 fragments are well known to the person skilled in the art and include those disclosed in International PCT Patent Publication WO 92/23224, Sawai et al., "Direct Production of the Fab Fragment Derived From the Sperm

Examples of techniques which can be used to produce scFv (single chain Fv fragments) are disclosed in Huston et al., “Protein Engineering of Single-Chain Fv Analogs and Fusion Proteins”, Methods in Enzymology, vol. 203:46-88 (1991), the contents of which are incorporated by reference.

In certain embodiments, antibody fragments can be derived from full-length antibodies by proteolytic digestion according to the method of Morimoto (Morimoto et al., “Single-step purification of Fab(ab')2 sub.2 fragments of mouse monoclonal antibodies (immunoglobulins G1) by hydrophobic interaction high performance liquid chromatography using TSKgel Phenyl-SPW” Journal of Biochemical and Biophysical Methods 24:107-117 (1992)). Antibody fragments can also now be produced directly by host cells (see Carter et al., “High level Escherichia coli expression and production of a bivalent humanized antibody fragment” Bio/Technology 10:163-167 (1992)).

In various further aspects, the present invention provides a method for the treatment and/or prevention of an inflammatory condition which is mediated in totality or in part by Toll-like Receptor 2, said method comprising the steps of:

- providing a therapeutically effective amount of a humanised antibody or binding fragment thereof in accordance with the present invention, and
- administering the same to a subject in need of such treatment.

In certain embodiments, the method involves the administration of a multivalent monospecific antigen-binding protein comprising two, three, four or more antibodies according to the invention.

A yet further aspect of the present invention provides a pharmaceutical composition comprising a humanised antibody, a humanised monoclonal antibody, an antigen binding portion thereof, immunoconjugate or bispecific molecule according to the present invention along with at least one pharmaceutically acceptable carrier, diluent or excipient.

In certain embodiments the formulation is a liquid formulation, a lyophilized formulation, a lyophilized formulation which is reconstituted as a liquid, or an aerosol formulation. In certain embodiments, the antibody in the formulation is at a concentration of: about 0.5 mg/ml to about 250 mg/ml, about 0.5 mg/ml to about 45 mg/ml, about 0.5 mg/ml to about 100 mg/ml, about 100 mg/ml to about 200 mg/ml, or about 50 mg/ml to about 250 mg/ml.

In certain embodiments, the formulation further comprises a buffer. Typically the pH of the formulation is from about pH 5.5 to about pH 6.5.

In certain embodiments, the buffer may comprise from about 4 mM to about 60 mM histidine buffer, about 5 mM to about 25 mM succinate buffer, or about 5 mM to 25 mM acetate buffer. In certain embodiments, the buffer comprises sodium chloride at a concentration of from about 10 mM to 300 mM, typically at around 125 mM concentration and sodium citrate at a concentration of from about 5 mM to 50 mM, typically 25 mM. In certain embodiments the formulation can further comprise a surfactant at a concentration of about 0% to about 0.2%. In certain embodiments the surfactant is selected from the group consisting of: but not limited to: polysorbate-20, polysorbate-40, polysorbate-60, polysorbate-65, polysorbate-80, polysorbate-85, and combinations thereof. In a preferred embodiment, the surfactant is polysorbate-20. In certain embodiments, the formulation further comprises about 0.001% to about 0.05% Tween and may further comprise sodium chloride at a concentration of about 125 mM and sodium citrate at a concentration of about 25 mM.

In certain embodiments, the pharmaceutical composition may further comprise, or be administered to a subject along with at least one immunomodulatory compound, such as an immune suppressant compound, a secondary antibody or fragment thereof, or a recombinant protein.

The antibody and binding members of the present invention may also be used in diagnosis, for example in the in vivo diagnosis and imaging of disease states involving Toll-like Receptor 2, where the antibody of the invention can be used to target and bind to cells expressing Toll-like Receptor 2. Furthermore, in certain embodiments, a secondary molecule or compound may be conjugated to the antibody of the invention for use in targeting that secondary molecule or compound to cells which express Toll-like Receptor 2.

In certain further aspects, the present invention provides a kit for the treatment or prevent of a Toll-like Receptor 2 mediated inflammatory conditions or disease. In certain embodiments, the kits comprise an antibody according to the present invention or an antigen binding fragment thereof that is capable of binding to Toll-like Receptor 2 and antagonising its functional activity, and instructions for the administration of the same to a patient.

According to a yet further aspect there is provided a humanised neutralising antibody or an antigen binding portion thereof, wherein the antibody specifically binds to mammalian Toll-like Receptor 2 with a Kd of 1x10^{-8} or less, but does not bind to CD32 (Fc gamma receptor II), wherein the antibody specifically binds to the same epitope present on the extracellular domain of Toll-like Receptor 2 as that bound by the commercially available antibody designated T2.5.

According to a yet further aspect there is provided an isolated monoclonal antibody, or antigen binding portion thereof, which binds an epitope on mammalian Toll-like Receptor 2 with a Kd of 1x10^{-8} or less and which does not bind to CD32 (Fc gamma receptor II), wherein the epitope is recognised by a reference antibody, wherein the reference antibody comprises a heavy chain variable region comprising the amino acid sequence of SEQ ID NO:4 and a light chain variable region comprising the amino acid sequence of SEQ ID NO:1.

According to a yet further aspect there is provided an isolated human monoclonal antibody, or an antigen binding portion thereof, which specifically binds mammalian Toll-like Receptor 2 and exhibits the following properties:

- binds to mammalian Toll-like Receptor 2 with a Kd of 1x10^{-8} or less,
- does not bind to CD32 (Fc gamma receptor II)
- is cross-reactive to human Toll-like Receptor 2, murine Toll-like Receptor 2 and monkey Toll-like Receptor 2.

Toll-like Receptor 2 and monkey Toll-like Receptor 2. Fab Binding Members

In certain embodiments of the foregoing aspects of the invention, an antibody fragment or an antigen binding portion of an antibody is provided by the invention. Examples of binding fragments include a Fab, Fab', or Fab(ab')2 fragment, which is a monovalent fragment consisting of, or consisting essentially of the VL, VH, CL and CH1 domains of a heterotetrameric antibody. In certain embodiments, the VL domain has an amino acid sequence of SEQ ID NO:1, and the VH domain has an amino acid sequence of SEQ ID NO:4. In certain embodiments, the CL and CH1 domains are based on
the amino acid sequence of a CL and CH1 domain of an immunoglobulin of the subclass IgG and isotype IgG4, or of CL and CH1 domains as shown in SEQ ID NO:5 of FIG. 5. In certain embodiments, the Fab fragment of this embodiment of the invention can be used for the treatment or prophylaxis of conditions including, but not limited to psoriasis, dermatitis, and ocular disease including uveitis and AMD (age-related macular degeneration).

Single Domain Binding Members

In addition to providing a humanised monoclonal antibody which has binding specificity to TLR2 and which antagonises TLR2 function, the present invention further extends to binding members other than antibodies comprising a pair of binding domains based on the amino acid sequence of a VL (light chain variable) region as defined in SEQ ID NO:1 and an amino acid sequence of a VH (heavy chain variable) region as defined in SEQ ID NO:4. In particular, the invention extends to single binding domains which are based on either the VL or VH region of the humanised antibodies of the invention.

Accordingly, in certain further embodiments of the present invention, there is provided a binding member comprising, consisting or consisting essentially of a single binding domain derived from the humanised antibody of the invention. In certain embodiments, the single binding domain is derived from the amino acid sequence of the VH (heavy chain variable domain) as defined in SEQ ID NO:4. Such a binding domain may be used as a targeting agent to TLR2, as it is known that immunoglobulin VH domains are capable of binding to target antigens in a specific manner.

Modification of CDR Residues

It will be appreciated by those skilled in the art that the sequences of the complementarity regions (as defined in SEQ ID NO:7, 8, 9, 10, 11 and 12), as well as sequences of the hypervariable and variable regions can be modified without losing the ability to bind specifically to TLR2. For example, CDR regions of binding members derived from the humanised antibodies of the present invention can be either identical or highly homologous (e.g. 95% sequence identity or higher) to the amino acid sequences defined herein in SEQ ID NO:7, 8, 9, 10, 11 and 12. As herein defined, by the term "highly homologous" it is meant that from 1 to 5 amino acid substitutions may be made to the sequences of the CDRs. In certain embodiments, the degree of homology which exists between respective CDRs, hypervariable regions or variable regions and their non-modified counterparts will be at least 80%, preferably 90%, or more preferably at least 95% and most preferably greater than 98%. Such modified sequences fall within the scope of the present invention in instances where the modified or homologous binding member retains the ability to specifically bind to TLR2 and antagonise its functional activity.

Polynucleotides

In various further aspects, the present invention extends to polynucleotides, and in particular isolated polynucleotides, which encode the humanised antibodies, antibody fragments and binding members of the present invention.

Accordingly in a further aspect of the present invention there is provided a polynucleotide which encodes the amino acid sequence of SEQ ID NO:1 and/or SEQ ID NO:4. In certain embodiments, the polynucleotide is an isolated polynucleotide.

As defined herein, a "polynucleotide" includes any polynucleotide or polydeoxyribonucleotide, which may be unmodified RNA or DNA, or modified RNA or DNA, including without limitation, single and double stranded RNA, and RNA which is a mixture of single and double stranded regions.

A polynucleotide of the invention, e.g. a polynucleotide which encodes a polypeptide or polypeptides comprising the amino acid sequence of SEQ ID NO:1 or SEQ ID NO:4, includes allelic variants thereof and/or their complements including a polynucleotide that hybridises to such nucleotide sequences under conditions of moderate or high stringency.

In various further aspects, the invention extends to an expression vector comprising a polynucleotide which encodes a polypeptide comprising SEQ ID NO:1 and/or SEQ ID NO:4. Furthermore, the invention extends to a host cell transformed with such a vector.

Hybridoma Cell Lines

A yet further aspect of the present invention provides a hybrid cell line (hybridoma), which expresses an antibody having a heavy chain variable domain amino acid sequence of SEQ ID NO:1 and a light chain variable amino acid sequence of SEQ ID NO:4.

BRIEF DESCRIPTION OF THE FIGURES

The patent or application file contains at least one drawing executed in color. Copies of this patent or patent application publication with color drawing(s) will be provided by the Office upon request and payment of the necessary fee.

FIG. 1A shows SEQ ID NO:1 which is the amino acid sequence of the variable domain of a light chain of an antibody according to the invention. FIG. 1B shows the variable light chain nucleotide sequence (SEQ ID NO:17) and the deduced amino acid sequence (SEQ ID NO:18) which has been numbered according to Kabat.

FIG. 2A shows SEQ ID NO:4 which is the amino acid sequence of the variable domain of a heavy chain of an antibody according to the invention. FIG. 2B shows the variable heavy chain nucleotide sequence (SEQ ID NO:19) and the deduced amino acid sequence (SEQ ID NO:20) which has been numbered according to Kabat.

FIG. 3 shows SEQ ID NO:2 which depicts the amino acid sequence of the light chain of an antibody according to the invention.

FIG. 4 shows SEQ ID NO:3 which shows a nucleic acid sequence which can be translated to encode the amino acid sequence of SEQ ID NO:2.

FIG. 5 shows SEQ ID NO:5 which is the amino acid sequence of the heavy chain of an antibody according to the invention.

FIG. 6 shows SEQ ID NO:6 which is a nucleic acid sequence which can be translated to encode the amino acid sequence of SEQ ID NO:5.

FIG. 7 shows SEQ ID NO:15 which provides the amino acid sequence of human Toll-like Receptor 2.

FIG. 8 shows SEQ ID NO:16 which provides the amino acid sequence of murine Toll-like Receptor 2.

FIG. 9 shows that OPN-305 mediated Toll-like Receptor 2 antagonism is not dependent on the antibody binding to CD32, with group 1 showing the addition of a control goat antibody, group 2 showing the addition of a goat anti-hCD32a blocking antibody, and group 3 showing the addition of a goat anti-hCD32b blocking antibody.

FIG. 10 shows that Toll-like Receptor 2 antagonism mediated by the OPN301 monoclonal antibody is dependent upon the antibody binding to CD32 (FIG. 10A), whereas OPN-305 mediated Toll-like Receptor 2 antagonism is not dependent upon the antibody binding to CD32 (FIG. 10B). In FIG. 10A, column A relates to cells stimulated with Pam3CSK4 only.
Column B relates to cells exposed to the OPN-301 antibody. Column C relates to OPN301 antibody along with 0.4 μg/ml anti-CD32a/b or a control goat IgG antibody. Column D relates to OPN301 antibody along with 2 μg/ml anti-CD32a/b antibody or a control goat IgG antibody. Column E relates to OPN301 antibody, plus 10 μg/ml anti-CD32a/b antibody or a control goat IgG antibody. In FIG. 10B, column A relates to cells stimulated with Pam3CSK4 only. Column B relates to cells exposed to the OPN-305 antibody. Column C relates to OPN305 antibody along with 0.4 μg/ml anti-CD32a/b or a control goat IgG antibody. Column D relates to OPN305 antibody along with 2 μg/ml anti-CD32a/b antibody or a control goat IgG antibody. Column E relates to OPN305 antibody, plus 10 μg/ml anti-CD32a/b antibody or a control goat IgG antibody.

FIG. 11 shows the results of FACS analysis which shows that OPN-305 has binding specificity for human Toll-like Receptor 2 (FIG. 11A), whereas an IgG4 isotype control antibody did not compete with OPN-305 to bind to Toll-like Receptor 2 (FIG. 11B).

FIG. 12 shows that OPN-305 (OPN-305-21) suppresses murine TLR2 responses in an equivalent manner to the murine OPN-301 antibody.

FIG. 13 shows 3 FACS analysis traces that show that OPN-305 binds to monocytes TLR2 which is expressed on granulocytes (FIG. 13A) and monocytes (FIG. 13B), but not lymphocytes (FIG. 13C).

FIG. 14 shows 2 FACS analysis traces that show that OPN-305 competes with the anti-TLR2 murine monoclonal antibody OPN-301 for binding to murine TLR2, wherein FIG. 14(A) shows the results for granulocytes and FIG. 14(B) shows the results for monocytes.

FIGS. 15 (A) and (B) show traces of antibody samples which have been purified by size exclusion chromatography on a 1/60 Sephacryl S2000 column. FIG. 15(A) showing an anti-TLR2 chimeric antibody, FIG. 15(B) showing the OPN305 antibody (VK5/VH4). In each case the monomer peak spanning fractions B8 to B4 was collected.

FIG. 16 shows the pre-screen of test samples for cytotoxicity and T cell modulation activity tested in 4 donor samples. Sample 1 (first column of each group [black bar]) is a chimeric anti-TLR2 antibody, sample 2 (second column of each group of results [white coloured bar]) is VK5/VH4 (OPN305), sample 3 (third bar [dark grey]) is a comparative antibody designated VK5/VH5 along with KHL, while sample 4 (fourth bar on right hand side of each group [light grey]) is a KHL only control. The results show viable cell counts on day 7. The S.I.s of samples incubated in the presence of KHL were compared to those of KHL alone. S.I.s were averaged over the four day sampling period. The cut-off for determining positive responses with an S.I. 2.

FIGS. 17 (A), (B) and (C) show 3 bar charts showing the results of episcereen testing. Chimeric anti-TLR2, VK5/VH4 and VK5/VH5 antibodies were tested in Episcereen™ time course T cell assays using PBMC from 21 donors. Bulk cultures of PBMC incubated with test antibodies were sampled on days 5, 6, 7 and 8, and pulsed with 3H-Thymidine. Cells were harvested and incorporation of radioactivity measured by scintillation counting. Results for each triplicate sample were averaged and normalized by conversion to Stimulus Index (SI). The SI for each time point with each donor is shown above for (a) the chimeric antibody, (b) the OPN-305 anti-TLR2 antibody (designated VK5/VH4), (c) a comparative anti-TLR2 antibody designated VK5/VH5. The cut-off for determining positive responses with an SI ≥2 is highlighted by the thick black horizontal line and significant responses (p<0.05 in a student’s t-test) are indicated (*).

FIG. 18 shows a comparison of immunogenicity predicted using EPISCREE™ Technology and immunogenicity observed in a clinical setting. 16 therapeutic proteins were tested for their relative risk of immunogenicity using EPISCREE™ technology. Results were plotted against the frequency of immunogenicity (anti-therapeutic antibody responses) observed for each protein when used in the clinic (data sourced from PubMed). The line of regression and the correlation coefficient is shown.

FIG. 19 shows an alignment of the light chain variable region amino acid sequence of the OPN-305 anti-TLR2 monoclonal antibody (SEQ ID NO:22) and the T2.5 murine anti-TLR2 monoclonal antibody (SEQ ID NO:21), wherein the determined sequence identity is shown to be 89.2%.

FIG. 20 shows an alignment of the heavy chain variable region amino acid sequence of the OPN-305 anti-TLR2 monoclonal antibody (SEQ ID NO:24) and the T2.5 murine anti-TLR2 monoclonal antibody (SEQ ID NO:23), wherein the determined sequence identity is shown to be 88.1%.

FIG. 21 shows that complete inhibition of TLR2 dependent signalling is achieved with less than maximal receptor binding of OPN-305. Inhibition of NF-kB activity is observed in a dose dependent manner following treatment with Pam3CSK4 (FIGS. 21A and B). OPN305 almost completely inhibits NF-kB activity at concentrations of 2 μg/ml (FIG. 21C).

FIG. 22A depicts NF-kB dependent SEAP activity versus [Pam3CSK4], while FIG. 22B depicts a Lineweaver Burk Plot of 1/V versus 1/S.

FIG. 23 shows 3 charts A, B and C, depicting that the Toll-like Receptor mediated responses to flagellin (TLR5, FIG. 23C) and LPS (TLR4, FIG. 23B) were unaffected when compared to control cells not exposed to OPN-305. As expected, Toll-like Receptor 2 mediated responses to Pam3CSK and FSL-1 were blocked by OPN-305 (FIG. 23A). This suggests that OPN-305 is not bringing about any unexpected increase or decrease in TLR4 or TLR5 responsiveness to ligands.

FIG. 24 shows that the OPN-305 monoclonal antibody inhibits Pam3CSk4 induced sepsis. Groups of female BALB/c mice (n=4) were treated with OPN-305 at the doses indicated 30 minutes prior to treatment with 100 μg of Pam3CSk4.

FIG. 25 shows that OPN305 inhibits Pam3CSk4 induced sepsis. In this experiment, OPN305 was administered intravenously 30 minutes prior to intraperitoneal administration of 100 μg of Pam3CSk4. Four hours later, mice were sacrificed by lethal anaesthesia and blood was taken. Serum was derived and cytokine concentrations were determined by ELISA. Sera was diluted at 1:10 for KC (FIG. 25A) and 1:5 for IL-6 (FIG. 25B) ELISAs.

FIG. 26 shows TLR2 is expressed on rat alveolar macrophages (NR8383), and is detected using OPN305. (A) Unstained cells, (B) positive control; polyclonal rabbit anti-rat TLR2 primary antibody, secondary antibody was anti-rabbit Alexa-Fluor 488; (C) Cells treated with polyclonal human IgG4, secondary antibody was human anti-IgG4 PE; (D) OPN305 stained cells, secondary antibody anti-human IgG4 PE.

FIG. 27 shows TLR2 is expressed on porcine PBMCs and is stained by OPN305. PBMCs were purified by separation using Ficoll. A-C represent PBMCs from Pig 666 and D-F is from Pig 488. A, D is unstained; B, E is labelled with polyclonal human IgG4, followed by secondary staining with PE
labelled anti-human IgG4; C, F is labelled with OPN305, followed by PE labelled anti-human IgG4.

DETAILED DESCRIPTION OF THE INVENTION

The present invention provides a fully human monoclonal antibody which has binding specificity for Toll-like Receptor 2 and which, when bound to Toll-like Receptor 2, antagonises Toll-like Receptor 2 functional activity. The invention further provides binding fragments derived from the fully human antibody and further to binding members which comprise, consist or consist essentially of the variable light chain domain amino acid sequence of SEQ ID NO:1 and/or the variable heavy chain domain amino acid sequence of SEQ ID NO:4.

By the term “antagonising Toll-like Receptor 2 function”, or similar terms, such as “Toll-like Receptor 2 antagonist” or “agonist of Toll-like Receptor 2” it is meant that the antibody, fragment or binding member binds specifically to Toll-like Receptor 2 and inhibits or blocks the binding of a ligand or binding compound to Toll-like Receptor 2, which would in turn cause activation of Toll-like Receptor 2, e.g. a Toll-like Receptor 2 ligand. The antibody, fragment or binding member may further inhibit Toll-like Receptor 2 activation and function by inhibiting or suppressing intracellular signalling mediated by Toll-like Receptor 2 following the binding of a Toll-like Receptor 2 ligand. By “Toll-like Receptor 2 activation and downstream mediated signalling” it means any intracellular signalling pathway which is induced by activation of Toll R2. The signalling pathway may be a Toll R2 specific pathway, or may be a “shared” signalling pathway, for example where the signalling pathway may be activated by other sources, for example, by means of the activation of receptors other than Toll R2 which contribute to the activation of mediators of the immune response such as the transcription factor NF-kappaB.

Toll R2 is known to dimerise into 2 functional heterodimers. In particular, Toll R2 is known to form a heterodimer with either Toll-like Receptor 1 or Toll-like Receptor 6. It is possible that further heterodimers are formed with Toll-like Receptor 4 (Toll R4, Toll R-4) and Toll-like Receptor 10 (Toll R10, Toll R-10). It is thought that this dimerisation is associated with a discrimination that results in the binding of Toll R2 by different microbial-derived ligands. The inventors has identified that the humanised antibodies of the invention function to antagonise Toll R2 function irrespective of whether Toll-like Receptor 2 forms a heterodimer with Toll-like Receptor 1 or Toll-like Receptor 6.

Antibody Binding Epitope

The humanised antibodies of the invention, or the fragments thereof, or binding members based thereon selectively bind to Toll-like Receptor 2 and antagonise its function. Monoclonal antibodies can block the activation of a receptor by its ligand by binding near to the ligand binding site of the receptor, this resulting in steric hindrance which precludes access of the ligand to the ligand binding site.

Without wishing to be bound by theory, the inventor has identified the binding site which is bound by the humanised antibodies according to the present invention. The antibody binds to an epitope which comprises residues derived from both the N-terminal and C-terminal domains of the mature extracellular domain of Toll-like receptor 2 (Toll R2). In certain embodiments, the epitope comprises amino acid residues 19 to 39 of the N-terminal of Toll-like Receptor 2 as determined from the 5 linked amino acid sequence of Toll-like Receptor 2, said amino acids being KEISSNQALSCDRN-GICKGS (SEQ ID NO:13). The binding epitope further comprises amino acids 538 to 549 of Toll-like Receptor 2 as present at the C-terminal region of the amino acid sequence of SEQ ID NO:1, this sequence comprising the amino acids CSCEFLSFTQEQEQ (SEQ ID NO:14).

Cross-Reactivity

Typically, the Toll R2 which is antagonised by the antibodies, antibody fragments or binding members of the invention is a mammalian Toll R2 (or a functional variant thereof), e.g., human Toll R2 or murine Toll R2. In certain embodiments, the Toll R2 antagonised is the human form of Toll R2 having the amino acid sequence as defined in FIG. 7 as SEQ ID NO:15, this comprising the 784 amino acid full length human Toll-like Receptor sequence as defined as Genbank Accession Number AAC 34133 (URL www.ncbi.nlm.nih.gov).

In certain further embodiments, the Toll-like Receptor 2 is murine Toll R2, this comprising the amino acid sequence defined FIG. 8 as SEQ ID NO:16, as derived from Genbank Accession Number NP_036035 (Mus musculus).

In certain further embodiments, the antibodies, antibody fragments or binding members of the invention serve to antagonise the functional activity or signalling of Toll-like Receptor 2 expressed on monkey cells.

In certain further embodiments, the antibody may have a dissociation constant (Kd) selected from the group consisting of: (i) a dissociation constant between 10^{-7}M and 10^{-11}M, (ii) a dissociation constant of between 10^{-8}M and 10^{-12}M, (iii) a dissociation constant between 10^{-9}M and 10^{-13}M, (iv) a dissociation constant of between 10^{-11}M and 10^{-15}M.

Binding of an antibody of the invention to Toll-like Receptor 2 can therefore result in the blocking of intracellular signalling which is associated with the ligand/receptor interaction of Toll R2 and its ligand.

Antibody Structure

The antibody and antibody fragments of the invention are fully human. That is, the amino acid residues which comprise the antibody are derived from the human species as opposed to, for example, a mouse. The antibody of the invention is therefore less immunogenic than a murine antibody or a chimeric antibody, such as a mouse/human antibody.

The immunogenicity which results from the administration of a murine or chimeric antibody has proved to be the most significant barrier to the therapeutic use of monoclonal antibodies. Accordingly, the provision of a fully human antibody overcomes the problems associated with the provision of murine, or human/mouse chimeric antibodies, which, when administered to a subject more than once, can result in an immunogenic reaction, such as a HAMA response, being directed against the antibody. This response clears the murine or chimeric antibody from the subject’s serum, thereby preventing the antibodies reaching their target and producing their intended therapeutic effect. Accordingly, the fully human antibody of the present invention confers a significant advantage over such murine and chimeric antibodies.

One intrinsic cause of immunogenicity against an antibody are CD4+ T cells epitopes present on the antibody. Accordingly, the antibody and binding fragments of the present invention have been analysed to identify and modify any CD4+ T cell epitopes present on the antibody or antibody fragment. This process further reduces the immunogenicity of the antibody and antibody fragments of the invention.

Moreover, the antibody or antibody fragments of the invention may be subject to one or more techniques which may further be used to ensure that an immunogenic response is not mounted against the antibody when administered to a subject.
Examples of such techniques will be well known to the person skilled in the art and include, but are not limited to, deimmunisation, gene shuffling and PE/Gylation.

Furthermore, in order to enhance the biologic function or therapeutic activity of an antibody or antibody fragment of the invention, further optimisation techniques may be employed. Such techniques include, but are not limited to modifying the following attributes of the antibody: potency, affinity, binding specificity, K(on) (association rate constant), K(off) (dissociation rate constant), thermodynamic stability, solubility, serum half-life, expression, folding kinetics, protease susceptibility, Fc region effector function and drug recycling. The biological function or therapeutic activity which may be modulated includes, but is not limited to: enhancement of efficacy, improved pharmacokinetic profile, enhanced patient convenience, decreased cost of goods, improved safety profile, reduced immunogenicity and extended shelf-life.

Treatment of TLR2-Mediated Disease

The humanised antibodies, antibody fragments and binding members of the invention may induce immunosuppression (suppression of an immune response, most particularly a pro-inflammatory immune response), in particular by suppressing Toll-like Receptor 2 mediated activation and signalling. This suppression of Toll-like Receptor 2 function has been identified by the inventors as having utility in the treatment or prevention of disease conditions in which Toll-like Receptor 2 activation and signalling contributes to the onset or progression of disease.

An antibody of the invention may be used in, for example, in vitro, ex vivo, and in vivo therapeutic methods.

In certain further aspects, the invention relates to the use of the antibodies, antibody fragments or binding members of the invention for the treatment of disease conditions mediated by Toll-like Receptor 2 activation and signalling.

Treatment of Ischemia

Accordingly, in a further aspect, the present invention provides a method for the treatment and/or prophylaxis of ischemia reperfusion injury or a condition caused thereby or associated therewith, the method comprising the steps of: providing a therapeutically effective amount of a humanised antibody, or binding fragment thereof as defined herein, and administering said compound to a subject in need of such treatment.

A yet further aspect of the present invention provides a fully humanised antibody according to the present invention, or a binding member derived therefrom for use in treating ischemia reperfusion injury or a cardiac inflammatory condition which is mediated in totality or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand. A yet further aspect provides the use of a humanised antibody according to the present invention, or a fragment thereof or a binding member derived therefrom in the preparation of a medicament for the treatment or prevention of ischemia reperfusion injury or a cardiac inflammatory condition which is mediated in totality or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.

In certain embodiments, the cardiac inflammatory condition results from the occurrence of reperfusion injury and can be selected from the group comprising, but not limited to: myocardial ischemia, ischemic heart disease, hypertension myocardial ischemia, congestive heart failure, tissue ischemia, organ ischemia, acute coronary syndrome, hypertrophy, cerebral infarction, myocardial infarction, arrhythmia, ischemia reperfusion injury (I/R injury).

Ischemia is caused when an organ or part of the body fails to receive a sufficient blood supply. An organ that is deprived of an adequate blood supply is said to be hypoxic. Reperfusion occurs when blood flow recommences to an organ following temporary deprivation. Reperfusion injury relates to damage which occurs to a tissue or an organ upon the return of the blood supply to a tissue following a period of ischemia. The absence of oxygen and nutrients during the period of ischemia results in a period of inflammation and oxidative damage when circulation returns. Examples of ischemia reperfusion injury include hypoxia, stroke, heart attack, chronic kidney failure or organ transplantation.

In certain embodiments, the methods of this aspect of the invention may be used for the treatment or prevention of ischemia reperfusion injury which may result from organ transplantation in a subject. In certain embodiments, the antibody of the invention can be used for the treatment and/or prevention of ischemia which may result from solid organ transplantation.

A yet further aspect of the present invention provides a method of reducing one or more biological activities of Toll-like receptor 2 (TLR2) in a TLR2 expressing cell or tissue implicated in ischemia reperfusion injury associated with solid organ transplantation in a subject, comprising: contacting the cell or tissue with a Toll-like Receptor 2 antagonistic antibody according to the present invention, in an amount sufficient to reduce one or more biological activities of TLR2 in the cell or tissue.

In certain embodiments the TLR2 expressing cell or tissue is a cell or tissue of the myocardium. In certain embodiments the TLR2 expressing cell or tissue is a cell or tissue involved with a reperfusion induced cardiac inflammatory condition selected from the group comprising, but not limited to: myocardial ischemia, ischemic heart disease, hypertension myocardial ischemia, congestive heart failure, tissue ischemia, organ ischemia, acute coronary syndrome, hypertrophy, cerebral infarction, myocardial infarction, arrhythmia, ischemia reperfusion injury (I/R injury).

In certain embodiments the method is performed on a human subject having, or at risk of having ischemia reperfusion injury.

A yet further aspect of the present invention extends to the use of an antibody according to the present invention, or a binding fragment thereof, for use in treating or preventing ischemia and reperfusion associated with solid organ transplantation.

Treatment of Autoimmune Disease

In a yet further aspect, the present invention provides a method for the treatment and/or prophylaxis of an autoimmune disease or condition associated therewith, the method comprising the steps of: providing a therapeutically effective amount of a humanised antibody, or binding fragment thereof as defined herein, and administering said compound to a subject in need of such treatment.

A yet further aspect of the invention provides a humanised antibody according to the present invention, or a binding member derived therefrom for use in treating an autoimmune disease which is mediated in totality or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.

A yet further aspect provides the use of a humanised antibody according to the present invention, or a binding member derived therefrom in the preparation of a medicament for the treatment or prevention of an autoimmune disease which is mediated in totality or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.
In certain embodiments, the autoimmune disease is autoimmune arthritis, in particular rheumatoid arthritis. In certain embodiments, the autoimmune disease is selected from the group comprising psoriasis, dermatitis. In certain further embodiments, the autoimmune disease is diabetes. Typically the diabetes is diabetes mellitus. In certain embodiments, the diabetes is type 1 diabetes mellitus. In certain further embodiments, the diabetes is type 2 diabetes mellitus.

In certain embodiments, the condition which results from the subject having diabetes may be termed a diabetic complication. Such diabetic complications may be acute complications, chronic complications or a combination of both.

Where the diabetic complication is an acute complication, the complication may be selected from the group comprising, but not limited to, retinopathy, neuropathy, peripheral circulation disorders, skin ulcers, polyuria, polydipsia, polyphagia, diabetic ketoacidosis (DKA) and hyperosmolar non-ketotic state. In certain further embodiments the condition may be a condition which results from any one of the preceding acute or chronic conditions and may include, but is not limited to, blindness, proteinuria, pain, numbness, psychosomatic, intermittent claudication and gangrene.

In certain further embodiments the diabetic complication may be a chronic complication such as vascular disease resulting from the chronic elevation of blood glucose levels leading to damage of the blood vessels (angiopathy). In such embodiments, where vascular damage occurs to small blood vessels, this can lead to micro-angiopathy, which can lead to one or more of diabetic retinopathy, diabetic neuropathy and diabetic nephropathy.

According to a still further aspect of the invention there is provided a method for treating or preventing an obesity associated disorder in a subject which is mediated in total or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.

A yet further aspect provides the use of a humanised antibody according to the present invention, or a binding member derived therefrom in the preparation of a medicament for the treatment or prevention of insulin resistance in a subject which is mediated in total or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.

A further aspect provides the use of a humanised antibody according to the present invention, or a binding member derived therefrom in the preparation of a medicament for the treatment or prevention of insulin resistance in a subject which is mediated in total or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.

A yet further aspect provides the use of a humanised antibody according to the present invention, or a binding member derived therefrom in the preparation of a medicament for the treatment or prevention of diabetes in a subject which is mediated in total or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.

A further aspect provides the use of a humanised antibody according to the present invention, or a binding member derived therefrom in the preparation of a medicament for the treatment or prevention of diabetes mellitus in a subject which is mediated in total or in part by Toll-like Receptor 2 activation by a Toll-like Receptor 2 ligand.

As herein defined, the terms “renal inflammation” and “renal disease” extend to conditions which are substantially characterised by the occurrence of inflammation within the kidney, or cells of the kidney, or where the occurrence of inflammation in the kidney is caused by a disease or an inflammatory condition which primarily affects a site in the body other than the kidney. In particular, inflammation may occur at a site including, but not limited to; the glomerulus, Bowman’s capsule or Bowman’s space. Typically, the inflammation results in at least partial impairment of kidney function and/or kidney failure.

In certain embodiments, the renal inflammation and disease includes “kidney disease”, wherein the term kidney disease generally refers to a disorder of at least one kidney in a human, wherein the disorder compromises or impairs the function of the kidney(s), this being characterised physiologically by, for example, the leakage of protein into the urine, or by the excretion of nitrogenous waste. The kidney disease may also result from a primary pathology of the kidney, such as injury to the glomerulus or tubule, or from damage to another organ, such as the pancreas, which adversely affects the ability of the kidney to perform biological functions, such
as the retention of protein. Thus, kidney disease in the human can be the direct or indirect effect of a disease condition which may affect other organs. Examples of diseases which affect the kidneys, but which do not specifically target the kidneys are diabetes and systemic lupus. The terms renal disease and kidney disease are used interchangeably herein with the phrase “diseases of the kidney”. The kidney disease can, for example, result from, or be a consequence of, any change, damage, or trauma to the glomerulus, tubules or interstitial tissue in either the kidney cortex or kidney medulla.

In certain embodiments, the kidney disease may also be a progressive kidney disease. The term “progressive kidney disease” as used herein refers to any disease of the kidney that over time (e.g., days, weeks, months, years) leads to a loss of kidney function. As herein defined, the term “kidney function” generally refers to a physiological property of the kidney, such as the ability to retain protein thereby preventing proteinuria (e.g., albuminuria). Kidney function can be assessed, for example, by glomerular filtration rate (e.g., creatinine clearance), excretion of protein in urine (e.g., albuminuria; blood urea nitrogen, serum or plasma creatinine, or any combination thereof.

Examples of specific conditions which fall within the meaning of the term “renal inflammation and disease” include, but are not limited to: renal disorders which include, but are not limited to: chronic renal failure, acute renal failure, heterologous nephrotoxic nephritis, glomerulonephritis, sclerosis of the glomeruli, systemic lupus erythematosus (SLE), diabetic nephropathy, diabetic nephropathy wherein the diabetic nephropathy accompanies sclerosis of the liver, and glomerulonephritis wherein the glomerulonephritis is accompanied by sclerosis of the liver.

In certain further embodiments, renal inflammation and disease may relate to an immune-mediated disease which affects the cells of the kidney and/or kidney function. Such conditions may include, but are not limited to: Immunoglobulin A nephropathy, membranoproliferative glomerulonephritis, mesangial proliferative glomerulonephritis, nonproliferative glomerulonephritis, membranous glomerulonephritis, minimal-change disease, primary focal segmental glomerulosclerosis (FSGS), fibrillary glomerulonephritis, immunotactoid glomerulonephritis, proliferative glomerulonephritis, progressive glomerulonephritis, anti-GBM disease, kidney ischemia, kidney vasculitis, including disease associated with anti-neutrophil cytoplasmic antibodies (ANCA) (e.g., Wegener granulomatosis), lupus nephritis cryoglobulinemia-associated glomerulonephritis, bacterial endocarditis, Henoch-Schönlein purpura, post-infectious glomerulonephritis. Hematologies C, diabetic nephropathy, myeloidosis, hypertensive nephrosclerosis, light-chain disease from multiple myeloma, secondary focal glomerulosclerosis, and hypertensive nephrosclerosis.

The term “renal inflammation and disease” also encompasses acute renal failure. Acute renal failure (“ARF”) refers to the clinical conditions associated with rapid, steadily increasing azotemia, with or without oliguria (<500 mL/day). The cause of ARF can be grouped into three diagnostic categories: prerenal (inadequate renal perfusion); postrenal (obstruction); and renal. The pathophysiology of ARF is complex and multifactorial. Current concepts suggest that ARF may result from direct renal tubular injury, renal ischemia or intra-tubular obstruction. Clinically, ARF results in diminished glomerular filtration and reduced secretion of metabolic waste products, water, and electrolytes. Fluid overload, electrolyte imbalances and the uremic syndrome result in organ dysfunction. Organ dysfunction may ultimately result in death.

In various further aspects, the present invention extends to methods of modulating a function (e.g., altering one or more biological activities of TLR2) in a TLR2-responsive cell and/or tissue (e.g., a tissue which has undergone ischemia, which may undergo ischemia, or which may undergo reperfusion, a beta cell of the islets of Langerhans of the pancreas, or any further cell type which expresses TLR2 and which is implicated in a TLR2 mediated disease condition, or the development thereof). The method includes contacting the TLR2-responsive cell and/or TLR2-responsive tissue with a humanised antibody or binding fragment thereof as provided by the invention in an amount sufficient to antagonise the function of the TLR2-responsive cell or tissue, or the biological activity of TLR2 in the cell or tissue. In one embodiment, the contacting step can be effected in vitro, for example in a cell lysate or in a reconstituted system. Alternatively, the subject method can be performed on cells in culture, e.g., in-vitro or ex-vivo. For example, cells, such as purified or recombinant cells, can be cultured in-vitro and the contacting step can be effected by adding the TLR2 modulator to the culture medium. Typically, the TLR2-responsive cell is a mammalian cell, such as a human cell. In some embodiments, the TLR2-responsive tissue is a tissue which has undergone ischemia and which may undergo reperfusion, or is a cellular population associated therewith. In other embodiments, the method can be performed on cells present in a subject, e.g., as part of an in-vivo protocol, or in an animal subject (including, e.g., a human subject, or an in-vivo animal model). The in-vivo protocol can be therapeutic or prophylactic, and the inflammatory model can be, for example, a genetically modified model, such as an animal model having over expressed TLR2, or a mutation or deletion in a TLR receptor. For in vivo methods, the humanised antibody or fragment thereof can be provided alone or in combination with another agent, such as a secondary therapeutic, such as an anti-inflammatory drug, or a pharmaceutically acceptable carrier, excipient or diluent. Typically the antibody is administered to a subject suffering, or at risk of suffering from the TLR2-mediated condition, such as rheumatoid arthritis, ischemia reperfusion injury, diabetes or renal inflammation, in an amount sufficient to antagonise one or more TLR2 mediated activities or functions in the subject. In certain embodiments, the amount or dosage of the humanised anti-TLR2 antibody of the invention that is administered can be determined prior to administration by testing in-vitro or ex-vivo, the amount of antibody required to alter, e.g., decrease or inhibit, one or more functional activity of TLR2, said functional activity typically being one or more TLR2 biological activities described herein.

It is understood that any of the above therapeutic methods may be carried out using an immunomodulator of the invention in place of or in addition to the anti-TLR2 antibodies, or antibody binding fragment of the invention.

In certain further aspects, the invention extends to the use of the antibodies of the present invention in diagnostic applications. As such, a further aspect of the invention provides a method of diagnosing a disorder associated with increased expression of Toll-like Receptor 2. In certain embodiments, the method comprises contacting a test cell with an anti-TLR2 antibody of the invention; determining the level of expression (either quantitatively or qualitatively) of TLR2 by the test cell by detecting binding of the anti-TLR2 antibody to TLR2; and comparing the level of expression of TLR2 by the test cell with the level of expression of TLR2 by a control cell (e.g., a normal cell of the same tissue origin as the test cell or
a cell that expresses TLR2 at levels comparable to such a normal cell, wherein a higher level of expression of TLR2 by the test cell as compared to the control cell indicates the presence of a disorder associated with increased expression of TLR2. In certain embodiments, the test cell is obtained from an individual suspected of having a disorder associated with increased expression of TLR2. In certain embodiments, the disorder is an inflammatory disorder or immune mediated disorder, as described hereinafter.

Therapeutic Efficacy

The inventor has identified that the humanised anti-TLR2 antibody which is provided herein is therapeutically more desirable than the anti-TLR2 murine monoclonal antibodies which are known in the art.

In addition to the structural differences which exist between the light and heavy chain variable domains of the humanised antibodies of the invention and the murine anti-TLR2 antibodies of the prior art, the inventor has also surprisingly identified a number of functional advantages conferred by the humanised antibody of the present invention which would make the use of such an antibody more preferable in a clinical setting.

Without wishing to be bound by the inventor has identified that, when compared to the 11G7 anti-TLR2 murine monoclonal antibody, the fully humanised antibody according to the present invention exhibits superior functional and clinical utility as the antibody antagonises TLR2 function irrespective of whether TLR2 forms a heterodimer with either TLR1 or TLR6.

In relation to the murine TLR2.1 antibody, the inventor has identified that the humanised antibody of the present invention is cross reactive to different mammalian forms of TLR2, such as human, murine, rat, pig and monkey, whereas the murine TLR2.1 antibody only exhibits binding specificity to human TLR2. Furthermore, the humanised antibody of the present invention includes no murine amino acid residues and accordingly, the likelihood of neutralising antibodies being generated against them when administered to a subject is minimal, when compared to the murine derived TLR2.1 antibody.

With regard to the T2.5 antibody, the inventor has surprisingly identified that the T2.5 antibody (a mouse Toll-like Receptor 2 (TLR2) antibody, derived from hybridoma clone T2.5, HyCult Biotechnology b.v., Cell Sciences, Canton, USA: catalogue number 1054) mediates antagonism of TLR2 activation and signalling, with this occurring in a CD32-dependent manner. The inventor has identified that the fully humanised antibodies of the present invention do not require CD32 in order to mediate the suppression of TLR2 signalling, that is, binding to CD32, for example, by the Fc region of the antibody does not have to occur, in order to mediate antagonism of the TLR2 receptor when bound by the Fab portion of the antibody. Accordingly, the antagonism of Toll-like Receptor 2 function which is mediated by the OPN-305 fully humanised monoclonal antibody of the present invention is mediated in a CD32 independent manner. This includes binding to both CD32a and CD32b. This surprising observation, which has been made by the inventor is clinically significant, as the fully humanised antibody of the present invention has potentially greater patient access.

Furthermore, the fully humanised antibodies of the present invention is predicted to bind to an epitope defined by residues present at the CD32 and C terminals of the TLR2 amino acid sequence. This is in contrast to WO 2005/028509 which states that the epitope bound by the T2.5 monoclonal antibody is located at the N-terminal (only) of the TLR2 sequence.

Furthermore, as exemplified in the comparative examples provided herein, the inventor has confirmed that the fully humanised antibody of the present invention exhibits a reduced immunogenicity profile, that is, that the antibodies are less immunogenic due to a lack of T cell epitopes. Accordingly, antibodies according to the invention will be very unlikely to have a neutralising antibody response raised against them when administered to a human subject. This functional characteristic means that the fully humanised antibody of the present invention is far more desirable for use in a clinical setting that the murine antibodies TL2.1, T2.5 and 11G7 which are known in the art, or to chimeric antibodies or to humanised antibodies which may be developed based on traditional CDR grafting techniques.

Antibodies

An “antibody” is an immunoglobulin, whether natural or partly or wholly synthetically produced. The term also covers any polypeptide, protein or peptides having a binding domain that is, or is homologous to, the binding domain of the humanised antibodies of the invention. Immunoglobulins typically have a heterotetrameric structure comprising two identical heavy chains and two identical light chains, linked together by disulfide bonds. Each heavy and light chain comprises a variable domain which confers the binding specificity of the antigen, with these domains being known as VH and VL domains for the heavy and light chains respectively. Each chain also comprises at least one constant domain, with the light chain having at a single constant domain, designated the CL domain, while the heavy domain comprises three constant domains, C1, C2 and C3. Some antibody isotypes additionally include a further constant domain referred to as the CH4 domain. In humans, there are 5 different classes of antibodies, namely: IgG, IgA, IgD, IgE and IgM.

The Fc region of an antibody typically comprises the last 2 heavy chain constant region domains of each chain. These domains form the Fc domain which is responsible for mediating the effector functions of the antibody, such as ADCC and complement fixation. The Fc region of the antibody also has a role in the circulatory half-life of the antibody. Modifications can be made to the Fc domain to modulate antibody function.

As antibodies can be modified in a number of ways, the term “antibody” should be construed as extending to any specific binding member, which has the same binding specificity as the humanised antibodies of the present invention. Accordingly, the term “antibody” extends to antibody fragments and homologues as well as to any polypeptide comprising an immunoglobulin binding domain which have binding specificity to Toll-like Receptor 2 and which serve to antagonise TLR2 function.

Furthermore, it is known that fragments of a whole antibody can perform the function of binding antigens. Examples of such binding fragments include, but are not limited to: (i) Fab fragments consisting of the VL, VH, CL and CH1 domains of a heterotetrameric antibody, (ii) F(ab)’2 fragments, a bivalent fragment comprising two Fab fragments linked by a disulfide bridge at the hinge region, (iii) Fab fragment, a Fab fragment with part of the hinge region, (iv) Fd fragments consisting of the VH and CH1 domains of a heterotetrameric antibody, (v) Fv fragments consisting of the VH and VL domains of a heterotetrameric antibody, (vi) scFv (single chain Fv molecules), wherein a VH domain and a VL domain are linked by a peptide linker, (vii) an isolated CDR, such as VHCDR3, and (viii) diabodies, these being multimers of polypeptides which may be multivalent or multispecific fragments produced by gene fusion techniques.
In certain further aspects, the invention also extends to bispecific antibodies. These may include conventional bispecific antibodies which may be prepared by chemical conjugation means, or by hybrid hybridoma cell lines. Alternatively, the bispecific antibodies may be derived from bispecific antibody fragments, such as scFv dimers or diabodies. In certain embodiments, scFv dimers may be used, rather than whole antibodies. Such diabodies can be constructed using only variable domains and therefore are provided without an Fc region, such a structure reducing the possible occurrence of a HAMA or anti-idiotypic immune response.

The amino acid residues in antibody domains are conventionally numbered according to a system devised by Kabat et al. (URL—www.kabatdatabase.com). This numbering is used in the present specification, except where otherwise indicated.

Peptidomimetics

The present invention further extends to peptidomimetics which are based on the antibodies of the present invention or binding fragments thereof. As used herein, the term “peptidomimetic” or “peptide mimetic”, refers to molecules which are not polypeptides, but which mimic aspects of their structures and which, in the context of the present invention, bind specifically to Toll-like Receptor 2, in a manner which results in the functional activity of Toll-like Receptor 2 being agonised. Hence, the invention extends to peptidomimetics based on the antibodies of the invention which act as Toll-like Receptor 2 antagonists.

Peptidomimetic antagonists can be prepared by conventional chemical methods (see e.g., Damewood J. R. “Peptide Mimetic Design with the Aid of Computational Chemistry” in Reviews in Computational Biology, 2007 Vol.9, pp. 1-80, John Wiley and Sons, Inc., New York, 1996; Kazmierski W. K., “Methods of Molecular Medicine: Peptidomimetic Protocols,” Humana Press, New Jersey, 1999). Peptidomimetics can be prepared that are Toll-like Receptor 2 antagonists, wherein said peptidomimetics are based on the antibodies of the present invention, and in particular based on the heavy and light chain variable regions. For example, polysaccharides can be prepared that have the same functional groups as peptides. Peptidomimetics can be designed, for example, by establishing the three dimensional structure of a peptide agent in the environment in which it is bound or will bind to a target molecule. The peptidomimetic comprises at least two components, the binding moiety or moieties and the backbone or supporting structure.

The binding moieties are the chemical atoms or groups which will react or form a complex (e.g., through hydrophobic or ionic interactions) with a target molecule, for example, with the amino acid(s) at or near the ligand binding site, such as the Toll-like Receptor 2 epitope comprising the amino acid sequence of SEQUID NO.3 or SEQUID NO.4. For example, the binding moieties in a peptidomimetic can be the same as those in a peptide or protein antagonist. The binding moieties can be an atom or chemical group which reacts with Toll-like Receptor 2 in the same or similar manner as the antibodies if the present invention. Examples of binding moieties suitable for use in designing a peptidomimetic for a basic amino acid in a peptide include nitrogen containing groups, such as amines, ammoniums, guanidines and amides or phosphonamides. Examples of binding moieties suitable for use in designing a peptidomimetic for an acidic amino acid include, for example, carbonyl, lower alkyl carboxylic acid ester, sulfonic acid, a lower alkyl sulfonic acid ester or a phosphorous acid or ester thereof.

The supporting structure is the chemical entity that, when bound to the binding moiety or moieties, provides the three dimensional configuration of the peptidomimetic. The supporting structure can be organic or inorganic. Examples of organic supporting structures include polysaccharides, polymers or oligomers of organic synthetic polymers (such as, polyvinyl alcohol or polylactide). It is preferred that the supporting structure possess substantially the same size and dimensions as the peptide backbone or supporting structure. This can be determined by calculating or measuring the size of the atoms and bonds of the peptide and peptidomimetic. In one embodiment, the nitrogen of the peptide bond can be substituted with oxygen or sulphur, for example, forming a polystyrene backbone. In another embodiment, the carbonyl can be substituted with a sulfonamido group or sulfanyl group, thereby forming a polyamide (e.g., a polysulfonamide). Reverse amides of the peptide can be made (e.g., substituting one or more —CONH-groups for —NHCO-group). In yet another embodiment, the peptide backbone can be substituted with a polysilane backbone.

These compounds can be manufactured by known methods. For example, a polystyrene peptidomimetic can be prepared by substituting a hydroxyl group for the corresponding α-amino group on amino acids, thereby preparing a hydroxy acid and sequentially esterifying the hydroxyacids, optionally blocking the basic and acidic side chains to minimize side reactions. Determining an appropriate chemical synthesis route can generally be readily identified upon determining the chemical structure.

Peptidomimetics can be synthesized and assembled into libraries comprising a few to many discrete molecular species. Such libraries can be prepared using well known methods of combinatorial chemistry, and can be screened to determine if the library comprises one or more peptidomimetics which have the desired activity. Such peptidomimetic antagonists can then be isolated by suitable methods.

Accordingly, certain further aspects of the present invention extend to peptidomimetics which are designed based on the paratopes of the Toll-like Receptor 2 binding antibodies of the present invention. In particular, such peptidomimetics are based on the structure of the CDR regions of the antibodies disclosed herein. Techniques for the production of such peptidomimetics will be well known to the person of skill in the art and include the method of Dougall et al. (“Design of pharmacologic agents based on antibody structure”, Trends in Biotechnology. 1994. 12. p 372-379). Further, the techniques of Saragovi et al. (Saragovi, et al., “Design and Synthesis of a Mimetic from an Antibody Complementarity-Determining Region”, Science 253:792-795 (1991) and Saragovi et al., “Loops and Secondary Structure Mimetics: Development and Applications in Basic Science and Rational Drug Design”, Biotechnology 10: 773-778 (1992)). Such peptidomimetics may, in particular be based on the CDR3 of the heavy chain. Williams, et al. (Williams et al., “Design of Bioactive Peptides Based on Antibody Hypervariable Region Structures”, J. Biol. Chem. 266: 5182-5160 (1991)), describes the isolation and synthesis of conformationally constrained peptides derived from the complementarity determining regions of the light chain of antibodies. This CDR is particularly important in the binding specificity of an antibody as a consequence of the complex genetic mechanism which influences its structure, which cause it to have medium or long loops which have diverse patterns of interactions. The conformational properties of peptide loops or reverse turns are considered important mediators in the biological activity of polypeptides. Turns provide for suitable orientations of binding groups essential for bioactivity by
stabilizing a folded conformation in a small molecule and may be involved in both binding and recognition sites.

The present invention further extends to antibody mimetics, such as Affibodies, domain antibodies, Nanobodies, Uni-Bodies, DARPin, Anticalins, Avimers, Versabodies, and Duo-calins which are based on the Toll-like Receptor 2 antibodies of the present invention. A wide variety of antibody mimetic technologies are known to the person skilled in the art. For example, so called, domain antibodies (Domantis, UK) are small functional binding units of antibodies which correspond to the variable regions of either the light or heavy chains of human antibodies. Directions for the production of such domain antibodies can be found in U.S. Pat. No. 6,291,158, U.S. Pat. No. 6,582,915 and U.S. Pat. No. 6,593,081. Nanobodies are antibody-derived therapeutic proteins which contain unique structural and functional properties of naturally occurring heavy chain antibodies found in camelds. Unibodies are a further antibody fragment technology, based upon the removal of the hinge region of IgG4 antibodies. The deletion of the hinge region results in a molecule which is approximately half the size of a traditional IgG4 antibody and which has a univalent binding region. Unibodies preserve the property of IgG4 antibodies of being inert and therefore not inducing immune responses. Hence, like IgG4 antibody based therapeutics, such as the embodiments of the antibodies of the present invention described herein, Unibodies can be used to antagonize specific functions of cells, but cell death will typically not occur as the Unibody, like an IgG4 antibody, will not mediate an immune response against the target to which it is bound. Unibodies are cleared from the body at a similar rate to IgG4 and bind with a similar binding affinity to their target antigens.

Further binding molecules include: affibody molecules (U.S. Pat. No. 5,831,012), DARPin (designated ankyrin repeat proteins) (International PCT Patent Application Publication WO 02/20565) and anticalins (U.S. Pat. No. 7,250,297 and WO 99/16873). Verabodies are a further antibody mimetic technology. Versabodies (Ammunix, US Patent Application Publication No. 200710191272) are small proteins, referred to as microproteins, of 3-5 kDa with greater than 15% cysteine residues, which form a high disulfide bond density scaffold which replaces the hydrophobic core which protein typically exhibit.

Avimers are another type of antibody mimetic. Avimers originate from the recombination of families of human serum proteins. They are single protein chains composed of modular binding domains, each of which is designed to bind to a particular target site. The avimers can bind simultaneously to sites on a single protein target and/or sites on multiple protein targets. Known as multi-point attachment or avidity, this binding mechanism mimics the way cells and molecules interact in the body, supports the generation of antagonists and agonists, and results in drugs with multiple functions and potent activity. Avimers libraries can be produced according to WO 2004/044011 incorporated herein by reference and particularly Example 6 on page 99, and for example US Patent Application (Publication) Nos. US 2005/0053973, US2005/0089932, US2005/0163401. Avimers libraries are also available commercially from Avidia Inc., Mountain View, Calif., USA.

Antibody Production

The antibodies and binding members of the invention may be produced wholly or partly by chemical synthesis. For example, the antibodies and binding members of the invention can be prepared by techniques which are well known to the person skilled in the art, such as standard liquid peptide synthesis, or by solid-phase peptide synthesis methods. Alternatively, the antibodies and binding members may be prepared in solution using liquid phase peptide synthesis techniques, or further by a combination of solid-phase, liquid phase and solution chemistry.

The present invention further extends to the production of the antibodies or binding members of the invention by expression of a nucleic acid which encodes at least one amino acid which comprises an antibody of the invention in a suitable expression system, such that a desired peptide or polypeptide can be encoded.

For example, a nucleic acid encoding the amino acid light chain and a second nucleic acid encoding an amino acid heavy chain can be expressed to provide an antibody of the present invention.

Accordingly, in certain further aspects of the invention, there is provided nucleic acids encoding amino acid sequences which form the antibodies or binding members of the present invention.

Typically, nucleic acids encoding the amino acid sequences which form antibodies or binding members of the present invention can be provided in an isolated or purified form, or provided in a form which is substantially free of material which can be naturally associated with it, with the exception of one or more regulatory sequences. Nucleic acid which encodes an antibody or binding member of the invention may be wholly or partially synthetic and may include, but is not limited to DNA, cDNA and RNA.

Nucleic acid sequences encoding the antibodies or binding members of the invention can be readily prepared by the skilled person using techniques which are well known to those skilled in the art, such as those described in Sambrook et al. "Molecular Cloning." A laboratory manual, cold Spring Harbor Laboratory Press, Volumes 1-3, 2001 (ISBN-0879695773), and Ausubel et al. Short Protocols in Molecular Biology. John Wiley and Sons, 4th Edition, 1999 (ISBN-0471250929). Said techniques include (i) the use of the polymerase chain reaction (PCR) to amplify samples of nucleic acid, (ii) chemical synthesis, or (iii) preparation of cDNA sequences. DNA encoding antibodies or binding members of the invention may be generated and used in any suitable way known to those skilled in the art, including taking encoding DNA, identifying suitable restriction enzyme recognition sites either side of the portion to be expressed, and cutting out said portion from the DNA. The excised portion may then be operably linked to a suitable promoter and expressed in a suitable expression system, such as a commercially available expression system. Alternatively, the relevant portions of DNA can be amplified by using suitable PCR primers. Modifications to the DNA sequences can be made by using site directed mutagenesis.

Nucleic acid sequences encoding the antibodies or binding members of the invention may be provided as constructs in the form of a plasmid, vector, transcrion or expression cassette which comprises at least one nucleic acid as described above. The construct may be comprised within a recombinant host cell which comprises one or more constructs as above. Expression may conveniently be achieved by cultivating, under appropriate conditions, recombinant host cells containing suitable nucleic acid sequences. Following expression, the antibody or antibody fragments may be isolated and/or purified using any suitable technique, then used as appropriate.

Systems for the cloning and expression of a polypeptide in a variety of different host cells are well known. Suitable host cells include bacteria, mammalian cells, yeast, insect and baculovirus systems. Mammalian cell lines available in the art for expression of a heterologous polypeptide include Chi-
nesque hamster ovary (CHO) cells, HeLa cells, baby hamster kidney cells and NS0 mouse myeloma cells. A common, preferred bacterial host is E. coli. The expression of antibodies and antibody fragments in prokaryotic systems such as E. coli is well established in the art. Expression in eukaryotic cells in culture is also available to those skilled in the art as an option for production of a binding member.

General techniques for the production of antibodies are well known to the person skilled in the field, with such methods being discussed in, for example, Kohler and Milstein (1975) Nature 256: 495-497; U.S. Pat. No. 4,376,110; Harlow and Lane, Antibodies: A Laboratory Manual, (1988) Cold Spring Harbor. Techniques for the preparation of recombinant antibody molecules are described in the above references and also in, for example, European Patent Number 0,368,684.

In certain embodiments of the invention, recombinant nucleic acids comprising an insert coding for a heavy chain variable domain and/or a light chain variable domain of antibodies or binding members are employed. By definition, such nucleic acids comprise encode single stranded nucleic acids, double stranded nucleic acids consisting of said coding nucleic acids and of complementary nucleic acids thereto, or these complementary (single stranded) nucleic acids themselves.

Furthermore, nucleic acids encoding a heavy chain variable domain and/or a light chain variable domain of antibodies can be enzymatically or chemically synthesised nucleic acids having the authentic sequence coding for a naturally-occurring heavy chain variable domain and/or for the light chain variable domain, or a mutant thereof.

An antibody of the invention may be produced by recombinant means, not only directly, but also as a fusion polypeptide with a heterologous polypeptide, which is preferably a signal sequence or other polypeptide having a specific cleavage site at the N-terminus of the mature protein or polypeptide. The heterologous signal sequence selected preferably is one that is recognized and processed (i.e., cleaved by a signal peptidase) by the host cell. For prokaryotic host cells that do not recognize and process a native antibody signal sequence, the signal sequence is substituted by a prokaryotic signal sequence selected, for example, from the group of the alkaline phosphatase, penicillinase, lpp, or heat-stable enterotoxin II leaders.

Isolated

The term “isolated”, when used in reference to the fully humanised antibodies of the invention, or to binding members derived therefrom, or polypeptides which encode the same, refers to the state in which said antibodies, binding members or nucleic acids (polynucleotides) are provided in an isolated and/or purified form, that is they have been separated, isolated or purified from their natural environment, and are provided in a substantially pure or homogeneous form, or in the case of nucleic acids, free or substantially free of nucleic acid or genes of origin other than the sequence encoding a polypeptide with the required function. Accordingly, such isolated antibodies, binding members and isolated nucleic acids will be free or substantially free of material with which they are naturally associated, such as other polypeptides or nucleic acids with which they are found in their natural environment, or the environment in which they are prepared (e.g. cell culture) when such preparation is by recombinant DNA technology practised in vitro or in vivo.

Antibodies, binding members and nucleic acids may be formulated with diluents or adjuvants and still, for practical purposes, be considered as being provided in an isolated form. For example the antibodies and binding members can be mixed with gelatin or other carriers if used to coat microtiter plates for use in immunoassays, or will be mixed with pharmaceutically acceptable carriers or diluents when used in diagnosis or therapy. The antibodies or binding members may be glycosylated, either naturally or by systems of heterologous eukaryotic cells (e.g. CHO or NS0 cells, or they may be (for example if produced by expression in a prokaryotic cell) unglycosylated.

Heterogeneous preparations comprising anti-κ TLR2 humanised antibody molecules also form part of the invention. For example, such preparations may be mixtures of antibodies with full-length heavy chains and heavy chains lacking the C-terminal lysine, with various degrees of glycosylation and/or with derivatized amino acids, such as cyclization of an N-terminal glutamic acid to form a pyroglutamic acid residue.

Administration

The monoclonal antibody or binding member of the present invention may be administered alone but will preferably be administered as a pharmaceutical composition which will generally comprise a suitable pharmaceutically acceptable excipient, diluent or carrier selected depending on the intended route of administration. Examples of suitable pharmaceutical carriers include; water, glycerol, ethanol and the like.

The monoclonal antibody or binding member of the present invention may be administered to a patient in need of treatment via any suitable route. Typically, the composition can be administered parenterally by injection or infusion. Examples of preferred routes for parenteral administration include, but are not limited to; intravenous, intracardial, intraarterial, intraperitoneal, intramuscular, intracavity, subcutaneous, transmucosal, inhalation or transdermal. Routes of administration may further include topical and enteral, for example, mucoal (including pulmonary), oral, nasal, rectal.

In embodiments where the composition is delivered as an injectable composition, for example in intravenous, intradermal or subcutaneous application, the active ingredient can be in the form of a parenterally acceptable aqueous solution which is pyrogen-free and has suitable pH, isotonicity and stability. Those of relevant skill in the art are well able to prepare suitable solutions using, for example, isotonic vehicles such as sodium chloride injection, Ringer’s injection or, Lactated Ringer’s injection. Preservatives, stabilisers, buffers, antioxidants and/or other additives may be included, as required.

The composition may also be administered via microspheres, liposomes, other microparticulate delivery systems or sustained release formulations placed in certain tissues including blood.

Examples of the techniques and protocols mentioned above and other techniques and protocols which may be used in accordance with the invention can be found in Remington’s Pharmaceutical Sciences, 18th edition, Gennaro, A. R., Lippincott Williams & Wilkins; 20th edition ISBN 0-912734-04-3 and Pharmaceutical Dosage Forms and Drug Delivery Systems; Ansel, H. C. et al. 7th Edition ISBN 0-683305-72-7, the entire disclosures of which is herein incorporated by reference.

The composition of the invention is typically administered to a subject in a “therapeutically effective amount”, this being an amount sufficient to show benefit to the subject to whom the composition is administered. The actual dose administered, and rate and time-course of administration, will depend on, and can be determined with due reference to, the nature and severity of the condition which is being treated, as well as factors such as the age, sex and weight of the subject being treated, as well as the route of administration. Further due
37

consideration should be given to the properties of the composition, for example, its binding activity and in-vivo plasma life, the concentration of the antibody or binding member in the formulation, as well as the route, site and rate of delivery.

Dosage regimens can include a single administration of the composition, or multiple administrative doses of the composition. The compositions can further be administered sequentially or separately with other therapeutics and medicaments which are used for the treatment of the condition for which the antibody or binding member of the present invention is being administered to treat.

Examples of dosage regimens which can be administered to a subject can be selected from the group comprising, but not limited to; 1 μg/kg/day through to 20 mg/kg/day, 1 μg/kg/day through to 10 mg/kg/day, 10 μg/kg/day through to 1 mg/kg/day. In certain embodiments, the dosage will be such that a plasma concentration of from 1 μg/ml to 100 μg/ml of the antibody is obtained. However, the actual dose of the composition administered, and rate and time-course of administration, will depend on the nature and severity of the condition being treated. Prescription of treatment, e.g. decisions on dosage etc., is ultimately within the responsibility and at the discretion of general practitioners and other medical doctors, and typically takes account of the disorder to be treated, the condition of the individual patient, the site of delivery, the method of administration and other factors known to practitioners.

DEFINITIONS

Unless otherwise defined, all technical and scientific terms used herein have the meaning commonly understood by a person who is skilled in the art in the field of the present invention.

Throughout the specification, unless the context demands otherwise, the terms ‘comprise’ or ‘include’, or variations such as ‘comprises’ or ‘comprising’, ‘includes’ or ‘including’ will be understood to imply the inclusion of a stated integer or group of integers, but not the exclusion of any other integer or group of integers.

As used herein, terms such as “a”, “an” and “the” include singular and plural referents unless the context clearly demands otherwise. Thus, for example, reference to an active agent” or “a pharmacologically active agent” includes a single active agent as well as two or more different active agents in combination, while references to “a carrier” includes mixtures of two or more carriers as well as a single carrier, and the like.

The terms “specifically binds”, “selectively binds” or “binding specificity” refer to the ability of the fully humanised antibodies or binding compounds of the invention to bind to a target epitope present on Toll-like Receptor with a greater affinity than that which results when bound to a non-target epitope. In certain embodiments, specific binding refers to binding to a target with an affinity that is at least 10, 50, 100, 250, 500, or 1000 times greater than the affinity for a non-target epitope. In certain embodiments, this affinity is determined by an affinity ELISA assay. In certain embodiments, affinity can be determined by a BIACore assay. In certain embodiments, affinity can be determined by a kinetic method. In certain embodiments, affinity can be determined by an equilibrium/solution method.

As used herein, the term “effective amount” or “therapeutically effective amount” means the amount of an agent, binding compound, small molecule, fusion protein or peptidomimetic of the invention which is required to suppress TLR2-mediated inflammation in the kidney or which reduces the severity of and/or ameliorates a TLR2 mediated renal disease or at least one symptom thereof or a condition associated therewith.

As used herein, the term “prophylactically effective amount” relates to the amount of a composition which is required to prevent the initial onset, progression or recurrence of a TLR2-mediated disease, or inflammatory condition, or at least one symptom thereof in a subject following the administration of the compounds of the present invention.

As used herein, the term “treatment” and associated terms such as “treat” and “treating” means the reduction of the progression, severity and/or duration of a TLR2 mediated condition or at least one symptom thereof, wherein said reduction or amelioration results from the administration of a binding compound which has specificity for the TLR2 binding epitope of the present invention. The term “treatment” therefore refers to any regimen that can benefit a subject. The treatment may be in respect of an existing condition or may be prophylactic (preventative treatment). Treatment may include curative, alleviative or prophylactic effects. References herein to “therapeutic” and “prophylactic” treatments are to be considered in their broadest context. The term “therapeutic” does not necessarily imply that a subject is treated until total recovery. Similarly, “prophylactic” does not necessarily mean that the subject will not eventually contract a disease condition.

As used herein, the term “subject” refers to an animal, preferably a mammal and in particular a human. In a particular embodiment, the subject is a mammal, in particular a human. The term “subject” is interchangeable with the term “patient” as used herein.

The present invention will now be described with reference to the following examples which are provided for the purpose of illustration and are not intended to be construed as being limiting on the present invention.

EXAMPLES

Example 1

Production of Fully Humanised Monoclonal Antibody

The TLR2 antagonistic antibodies of the present invention are typically fully humanised antibodies. That is, the antibodies are fully human in origin, and therefore do not contain regions or amino acid combinations derived from non-human species, such as mice.

One method of producing the fully humanised antibodies of the invention is through the use of composition human antibody technology (Antitope, UK) as described in International PCT Patent Application No. WO 2006/082406. Such antibodies are composite proteins comprising 2 or more segments of amino acid sequence derived from human antibodies. The segments can be selected such that the presence of T-cell epitopes in the final antibody is avoided, for example by screening the residues, particularly of the light and heavy chain variable regions to ensure that they do not comprise MHC class II binding motifs, or that they do not comprise residues which anchor the binding of peptides to MHC class II. Furthermore, in-silico methods of analysing the variable regions of the fully humanised antibody of the invention to ensure that no T cell epitopes are present.

In producing a fully humanised antibody using the composite human antibody technique, the final antibody is produced which comprises a composition of many sequence segments, all of which are human in origin, and all of which
are derived from different human antibodies. Briefly, the technique involves the steps of: analysing the heavy and light chain variable regions of a starting monoclonal antibody, for example a murine or chimeric antibody which has binding specificity for Toll-like Receptor 2 in order to identify the complementarity determining regions (CDRs). Protein models of the antibody variable regions are then generated using existing antibody structures as templates using Swiss PDB. These structural models are then analysed to identify important "constraining" amino acids in the variable domain regions of the original antibody that are likely to be essential for the binding properties of the antibody. Residues contained within the CDR regions (as defined using both the Kabat and Chothia definitions), together with a number of framework residues are typically important. Structural information from the protein model is used to identify and compare residues which are critical for antibody confirmation and binding with structurally equivalent residues from existing antibody structures and sequence databases. These amino acids may then be candidates for inclusion in one or more variants of the final humanised sequences. In preparing the antibody of the present invention, both the VH and VK sequences of the murine anti-TLR2 antibody on which the fully humanised antibody of the present invention is based (mouse Toll-like Receptor 2 (TLR2) antibody, derived from hybridoma clone T2.5, HyCult Biotechnology b.v., Cell Sciences, Canton, USA: catalogue number 1054) were seen to contain typical framework residues, especially in the VH where the antibody has very common sequence configurations at critical positions e.g. Kabat residues 45-49 (LEWYG) and 92-94 (CAR).

Sequences of the source monoclonal heavy and light chain variable region amino acid sequences are then compared with corresponding segments of human variable region sequences in order to identify potential heavy and light chain human sequences for possible inclusion in the final humanised sequence. Finally, fully humanised heavy and light chains are then designed entirely from segments of human variable region sequences.

The fully humanised antibody is designed and produced by firstly synthesising VH and VK region genes using a series of overlapping oligonucleotides that were annealed, ligated and PCR amplified to give full length synthetic V regions. The polynucleotide sequence was then cloned directly into a suitable expression vector, examples of which will be well known to the person skilled in the art, such as an expression vector system which encodes for an antibody, such as IgG. In the case of the expression vector used in the production of the OPN-305 antibody of the present invention, the expression vector system relates to an IgG4 derived sequence comprising a modified hinge region (a S241P substitution) as well as heavy chains and a kappa light chain. The heavy and light chains are thereafter stably transfected into NS0 cells via electroporation and selected using 200 nM methotrexate (Sigma, catalogue number M8407). Metotrexate resistant colonies were tested for IgG expression levels.

Although NS0 cells were used, any suitable cell line which is known to the person skilled in the art could be used. In particular the use of mammalian cells within a mammalian cell culture is preferred as a platform for the production of the antibodies and binding fragments of the invention. The use of mammalian cells are particularly preferred due to the N-glycosylation profile which is applied to the protein, as such glycosylation profiles are similar to those found on human proteins. Cell lines typically employed for mammalian cell culture include CHO, NSO hybridoma cells, baby hamster kidney (BHK) cells, and PER.C6™ human cells. The most commonly employed mammalian cell line used for mammalian cell culture at production scale volumes are the CHO and NS0 cell lines. These cell types are relatively easy to genetically engineer, have been extensively characterized, are relatively easy to grow at large scale, and can excrete high titers of recombinant proteins in solution. Both CHO and NS0 cell lines can produce high protein expression levels.

In addition to mammalian cell based protein expression platforms, the use of plant based expression systems, or transgenic animal systems may also be employed for the use of the production of the proteins of the invention.

The composite antibodies were then purified from cell culture supernatants on a Protein A sepharose column (GE Healthcare catalogue number 110034-93) and quantified by OD280 nm, using a calculated extinction coefficient where Ec(0.1%)=1.43. The purified antibodies were then tested in a competition ELISA assay to confirm binding to Toll-like Receptor 2. This binding may be compared to the binding of a reference antibody, such as a biotinylated form of a Toll-like Receptor 2 binding antibody upon which design of the fully human antibody was based. In particular, absorbance from the ELISA competition assay can be plotted against sample concentration and straight lines fitted through each of the data sets pertaining to the fully human and original biotinylated antibody. The equations of the lines were used to calculate the concentration required to inhibit biotinylated reference antibody binding to TLR2 by 50% (the so called, IC50 value). The IC50 value can be used to calculate the fold difference in binding efficiency. The determined binding efficiency can be an important determination of the specificity of the fully humanised antibody which is produced. Further comparisons, for example, comparing the fully humanised antibody to a chimeric or murine antibody, which has binding specificity for the same antigen, can also be performed.

Example 2

Determination of Binding Properties of OPN-305 Monoclonal Antibody

The invention has surprisingly identified that the T2.5 TLR2 antagonistic murine monoclonal antibody requires binding to CD32 in order to fully antagonise Toll-like Receptor 2 function. Experimentation was therefore performed to confirm that this functional limitation associated with the use of the T2.5 antibody was not also associated with the use of the OPN-305 monoclonal antibody in order to mediate its effect of neutralising Toll-like Receptor 2 biological activity.

Materials and Methods:

THP-1 cells are human peripheral blood monocyctes. In response to Toll-like receptor ligands, the transcription factor NF-kappaB and other transcription factors are activated in THP1 cells. The THP-1 Blue cell line has been stably transfected with a reported plasmid encoding the secreted embryonic alkaline phosphatase (SEAP) gene under the control of a promoter inducible by several transcription factors, such as NF-kappaB and AP-1. The THP-1 CD14 Blue cell line variant over expresses the cell surface protein CD14 for enhanced sensitivity. The resulting THP-1-CD14 Blue cells are resistant to the selectable markers Zeocin and blasticidin. Upon TLR stimulation, THP-1 Blue cells activate transcription factors and subsequently the secretion of SEAP which is then detectable using the QUANTI-Blue reporter system. QUANTI-Blue is a colorimetric enzymatic assay developed to determine secreted alkaline phosphatase (SEAP) activity in the supernatants of cell cultures. In the presence of SEAP, QUANTI-Blue medium changes to a purple-blue colour that
can easily be detected with the naked eye, or quantified by reading the optical density (OD) at 625-655 nm.

THP1 CD14 Blue cells were incubated with the OPN-305 anti-TLR2 monoclonal antibody (1 μg/ml) premixed with anti-CD32a antibody (RnD #AF1875) or the anti-CD32b antibody (RnD #AF1330) or goat IgG in the range 5 μg/ml-0.18 μg/ml for 5 minutes at 37°C, before stimulation with 20 ng/ml of the TLR1/TLR2 agonist Pam3CSK4. The OPN-305 monoclonal antibody is a fully humanised antibody having the light chain defined herein as SEQ ID NO:2 and a heavy chain as defined herein in SEQ ID NO:5.

Cells were then incubated overnight at 37°C. Supernatants were then removed and heat inactivated before addition of QUANTI-Blue (Invivogen, San Diego, USA). Colorimetric changes demonstrating NF-kB activation were measured at 650 nm using a luminometer.

The results are shown in FIG. 9, these results illustrating that the functional activity of OPN-305 as a Toll-like Receptor 2 antagonist is not blocked by the addition of anti-CD32a/b antibodies. This therefore indicates that the Toll-like Receptor 2 neutralising activity mediated by OPN-305 is not dependent on binding to CD32a or CD32b.

**Example 3**

Role of CD32 in Toll-Like Receptor 2 Antagonism

The results of Example 2 suggest that antagonism of Toll-like Receptor 2 by the OPN-305 fully humanised antibody of the invention is not dependent upon that antibody binding to CD32 (either CD32a or CD32b).

In order to confirm this, and to provide a comparison to other TLR2 antagonistic antibodies which are known in the field, such as the T2.5 murine TLR2 monoclonal antibody (OPN-301), further experimentation was performed.

**Materials and Methods:**

THP-1 CD14 Blue cells (Invivogen, San Diego, USA) were preincubated with doses of antibodies which block CD32a or CD32b.

The pre-incubated THP-1 CD14 Blue cells were incubated with increasing doses of (i) an anti-human Fc gamma RIIa (CD32a) antibody (R&D Systems, catalogue number AF1875, as used in the previous example), (ii) an anti-human Fc gamma RII (CD32) antibody (R&D Systems, catalogue number AF1330) or (iii) an isotopic control antibody (goat IgG (R&D systems, catalogue number AB-108-C). The cells then had either 200 ng/ml of the murine anti-TLR2 antibody T2.5 (OPN-301) or the fully humanised OPN-305 antibody added. The cells were then stimulated with 100 ng/ml of the TLR2 agonist Pam3CSK4 (Invivogen) overnight.

**Results**

NF-kB dependent SEAP production was measured in cell supernatants. FIG. 10A shows the results for cells exposed to the OPN-301 (T2.5 murine anti-TLR2 antibody). FIG. 10B shows the results for cells exposed to the OPN-305 fully humanised TLR2 antagonist antibody. In FIG. 10A, column A relates to cells stimulated with Pam3CSK4 only. Column B relates to cells exposed to the OPN-301 antibody. Column C relates to OPN-301 antibody along with 0.4 μg/ml anti-CD32a/b or a control goat IgG antibody. Column D relates to OPN-301 antibody along with 2 μg/ml anti-CD32a/b antibody or a control goat IgG antibody. Column E relates to OPN-301 antibody, plus 10 μg/ml anti-CD32a/b antibody or a control goat IgG antibody.

In FIG. 10B, column A relates to cells stimulated with Pam3CSK4 only. Column B relates to cells exposed to the OPN-305 antibody. Column C relates to OPN-305 antibody along with 0.4 μg/ml anti-CD32a/b or a control goat IgG antibody. Column D relates to OPN-305 antibody along with 2 μg/ml anti-CD32a/b antibody or a control goat IgG antibody. Column E relates to OPN-305 antibody, plus 10 μg/ml anti-CD32a/b antibody or a control goat IgG antibody.

A comparison of the data shown in the 2 figures clearly shows that TLR2 antagonism which is mediated by OPN-305 is not dependent on the antibody interacting with CD32, as blocking of CD32 with a CD32a or CD32b specific antibody has no effect on the TLR2 neutralising ability of OPN-305. In contrast, the murine T2.5 antibody (OPN-301) is shown to be dependent on binding to CD32 in order to mediate complete neutralisation of Toll-like Receptor 2 function activity. Without wishing to be bound by theory, the inventor therefore predicts that, in mediating TLR2 antagonism, the OPN-301 antibody binds to TLR2 and also CD32, this interaction with CD32 being necessary to mediate complete blocking of TLR2. There is therefore a functional difference between the mechanism of action used by the OPN-305 antibody and the OPN-301 antibody in relation to antagonising Toll-like Receptor 2 functional activity. Hence, the TLR2 antagonistic activity of OPN-301 can be blocked by blocking binding to CD32. However, blocking the ability of OPN-305 to bind to CD32, CD32a or CD32b does not affect it’s ability to antagonise Toll-like Receptor 2 functional activity.

**Example 4**

Confirmation of Toll-Like Receptor 2 Binding Specificity of OPN-305

The experiment was designed to confirm that the OPN-305 monoclonal antibody of the invention exhibits binding specificity for Toll-like Receptor 2 and in particular human Toll-like Receptor 2.

**Materials and Methods:**

HEK 293 (human embryonic kidney 293) cells stably transfected with Toll-like Receptor 1 and Toll-like Receptor 2 in order to allow formation of a TLR1/TLR2 heterodimer were incubated with 1.0 μg/ml of a biotinylated form of the murine anti-TLR2 antibody OPN-301 (T2.5) either alone or in the presence of 1.0 μg or 10 μg/ml of the fully humanised anti-TLR2 antibody OPN-305 or of an OPN-305 IgG4 isotype control antibody for 30 minutes on ice.

The OPN-301 monoclonal antibody is a murine IgG1 anti-TLR2 antibody (mouse Toll-like Receptor 2 (TLR2) antibody, clone T2.5, HyCult Biotechnology b.v., Cell Sciences, Canton, USA; catalogue number 1054).

The OPN-305 monoclonal antibody is a fully human antibody having the light chain defined herein in SEQ ID NO:2 and a heavy chain as defined herein in SEQ ID NO:5.

Cells were then washed and incubated with streptavidin conjugated to PE-Cy7 for a further 30 minutes. Binding was measured using FACSscalibur (Becton Dickinson). The results are shown in FIG. 11.

FIG. 11A relates to the binding of OPN-305 (labelled as variant 21). Moving from left to right, the darkest line of the first peak relates to the red line. The lighter line in the first peak relates to the green line. Moving right, the third, fourth and fifth peaks are the purple, blue and black peaks respectively. Binding of OPN-305 was demonstrated by a shift to the left of the blue and purple histograms (representing OPN-301 and OPN-305) compared to OPN-301 alone (black histograms) which demonstrates that OPN-305 is competing with OPN-301 for binding to human TLR2 on the HEK cells. In conclusion, FIG. 11A shows a dose dependent shift of the
peaks, this indicating competition in binding between OPN-301 and OPN-305 for human Toll-like Receptor 2.

FIG. 11B shows the results of binding with the IgG4 iso-type control. As the IgG4 isotype control antibody does not have binding specificity for TLR2, it does not compete for binding. There is therefore no shift in the black, purple or blue peaks, which are grouped together and represented as the second peak as shown on the right hand side of FIG. 11B. The peak on the left hand side relates to the red peak (darker line) and the green peak (lighter line). These results therefore confirm that OPN-305 has binding specificity for human Toll-like Receptor 2.

Example 5

Cross Reactivity of OPN-305 to Murine Toll-Like Receptor 2

Having determined in Example 4 that OPN-305 exhibits binding specificity to human Toll-like Receptor 2, this experiment assessed whether the OPN-305 monoclonal antibody exhibited Toll-like Receptor 2 intra-species cross-reactivity, which would allow OPN-305 to bind to other forms of mammalian Toll-like Receptor 2, such as murine Toll-like Receptor 2.

Materials and Methods:

J774 mouse macrophages were cultured at 1x10⁶/ml in the presence of 5 µg/ml OPN-305 (referred to as OPN-305-21), OPN-301 (T2.5) or the relevant isotype control antibody (murine IgG1 for OPN-301 and human IgG4 for OPN-305) for 6 hours at 37°C. Cells were exposed to the TLR2 agonist HKLM (Invivogen, San Diego, USA, catalogue number tlr2). HKLM is a freeze dried heat-killed preparation of Listeria Monocytogenes (LM), a facultative intracellular gram positive bacteria. Supernatants were then removed and murine TNF-α levels were measured by specific ELISA duoset from RnD systems (R&D Systems).

Results

The results are shown in the graph of FIG. 12. This shows that OPN-305 suppresses murine TLR2 responses in a broadly similar manner to the inhibition of OPN-301. Accordingly, OPN-305 is cross-reactive in that it binds to Toll-like Receptor 2 expressed on the surface or murine cells.

In conclusion, OPN-305 has been shown to suppress TNF-α secretion from murine J774 macrophages which were stimulated with a TLR2 agonist.

Example 6

Cross Reactivity of OPN-305 to Monkey Toll-Like Receptor 2

Further experiments were performed to determine the binding specificity of OPN-305 for Toll-like Receptor 2 expressed on monkey cells. This would identify whether the OPN-305 antibody was cross-reactive to a wider variety of mammalian forms of Toll-like Receptor 2, than just human and murine forms.

Binding of OPN-305 to monkey Toll-like Receptor 2 was determined by both direct antibody and competition binding assay.

(i) Direct Binding

Whole blood cells from cynomologus monkeys were incubated with 1.0 µg/ml of OPN-305 or an IgG4 isotype control antibody for 30 minutes at room temperature, then incubated with PharmLyse (BD Biosciences) to lyse red blood cells, followed by detection with FITC labelled anti-human IgG4.

The results are shown in FIGS. 13A, B and C. The different cell types were gated according to their forward and side scatter characteristics. FIG. 13A relates to granulocytes. FIG. 13B relates to monocytes. FIG. 13C relates to lymphocytes. Binding was demonstrated by a histogram shift to the right of cells incubated with OPN-305 (blue histogram—this being the peak at the right hand side of the group of peaks) compared to cells incubated with isotype control antibody (green histogram—this being the second peak; moving from left to right, this peak being in a lighter colour). The results in FIGS. 13A and 13B show that the blue peak has moved further to the right than the green peak. This shows that OPN-305 binds to monkey TLR2 which is expressed on granulocytes and monocytes. OPN-305 therefore exhibits a wide cross-reactivity to Toll-like Receptor 2 expressed on different cell types.

(ii) Competition Assay

Whole blood cells from cynomologus monkeys were incubated with 1.0 µg/ml biotinylated OPN-301 either alone or in the presence of 1.0 µg or 10 µg/ml OPN-305 or an IgG4 isotype control antibody (for OPN305) for 30 minutes at room temperature. Cells were then washed and incubated with streptavidin conjugated to PEcy7 for a further 30 minutes.

The OPN-301 monoclonal antibody is a murine IgG1 anti-TLR2 antibody (mouse Toll-like Receptor 2 (TLR2) antibody, clone T2.5, HyCult Biotechnology b.v., Cell Sciences, Canton, USA: catalogue number 1054).

The OPN-305 monoclonal antibody is a fully human antibody having the light chain defined herein as SEQ ID NO:2 and a heavy chain as defined herein in SEQ ID NO:5.

Binding was measured using FACScalibur from Becton Dickinson. The results are shown in FIGS. 14 A, B and C. FIG. 14A relates to granulocytes. FIG. 14B relates to monocytes. FIG. 14C relates to lymphocytes. Binding of OPN-305 is demonstrated by a shift to the left of the green histograms (representing OPN-301+OPN-305) compared to OPN-301 alone (black histograms) which demonstrates that OPN-305 is competing with OPN-301 for binding to monkey TLR2. Accordingly, it can again be seen that OPN305 is competing for monkey Toll-like Receptor 2 binding. This further confirms that OPN-305 is cross-reactive to Toll-like Receptor 2 expressed on human, mouse or monkey cells.

Example 7

Immunogenicity of OPN-305 Monoclonal Antibody

Analysis of the OPN-305 antibody was performed to determine the presence of immunogenic epitopes which might result in an immune response, such as a HAMA response, being raised against the antibody by the subject to whom the antibody is administered. As discussed herebefore, the presence of T cell epitopes is highly undesirable as the production of a neutralising antibody response against the antibody would result in that antibody no longer being suitable for administration to that patient for therapeutic purposes. The OPN-305 antibody was therefore screened to ensure that no T cell epitopes were evidently present.
Materials and Methods:
Preparation and Selection of Donor PBMC
Peripheral blood mononuclear cells (PBMC) were isolated from healthy community donor buffy coats (from blood drawn within 24 hours) obtained from the National Blood Transfusion Service (Addenbrooke’s Hospital, Cambridge, UK). PBMC were isolated from buffy coats by Lymphoprep™ (Axis-Shield, Dundee, UK) density centrifugation and CD8+ T cells were depleted using CD8+ RosetteSep™ (Stemcell Technologies Inc., London, UK). Donors were characterized by identifying HLA-DR haplotypes using a Biotech SSP-PCR based tissue-typing kit (Biotech, Landsteinerstrafge, Denmark) as well as determining T cell responses to a control antigen keyhole limpet haemocyanin (KLH) (Pierce, Rockford, USA). PBMC were then frozen and stored in liquid nitrogen until required.

A cohort of 21 donors was selected to best represent the number and frequency of HLA-DR alleles expressed in the world population. Analysis of the alleles expressed in the cohort against those expressed in the world population revealed that coverage of >85% was achieved and that all major HLA-DR alleles (individual alleles with a frequency >5% expressed in the world population) were well represented.

EpiScreen Time Course T Cell Proliferation Assays
The antibody was subjected to analysis to determine the presence of T cell epitopes as taught by international patent application No WO 2007/099341. PBMCs from each donor were thawed, counted and viability assessed. Cells were revived in room temperature AIMV culture medium (Invitrogen, Paisley, UK) and resuspended in AIMV to 4.6x10^6 PBMC/ml. For each donor, bulk cultures were established in which each of the 10 cultures were added to a 24 well plate. A total of 1 ml of each diluted test sample was added to the PBMC to give a final concentration of 50 μg/ml per sample. For each donor, a positive control (cells incubated with 100 μg/ml KLH) and a negative control (cells incubated with culture media only) were also included. For the first 4 donors, an additional control was included to test for modulation of T cell responses by the test samples, where test sample and KLH were both added to the PBMC. Comparison of these samples with KLH alone can be used to assess the effects of the test samples on proliferation. Cultures were incubated for a total of 8 days at 37°C with 5% CO2. On days 5, 6, 7 and 8, the cells in each well were gently resuspended and 3x100 μl aliquots transferred to individual wells of a round bottomed 96 well plate. The cultures were pulsed with 1 μCi [3H]-Thymidine (Perkin Elmer™, Waltham, Mass., USA) in 100 μl AIMV culture medium and incubated for a further 18 hours before harvesting onto filter mats (Perkin Elmer™, Waltham, Mass., USA) using a Tomtec Mach III cell harvester. Counts per minute (cpm) for each well were determined by MELTILLEX™ (Perkin Elmer™, Waltham, Mass., USA) scintillation counting on a Microplate Beta Counter in parallax, low background counting mode. In order to assess potential toxicity of the test samples, cell viability counts (using VIECELLO™ counter and trypan blue dye exclusion) were performed on samples of test cultures and media and KLH controls for the first 10 donors after 7 days incubation.

EpiScreen Data Analysis
For proliferation assays, an empirical threshold of a stimulation index (SI) equal to or greater than 2 (S1≥2) has been previously established whereby samples inducing proliferative responses above this threshold are deemed positive (where included, borderline S1s≥1.95 are highlighted). Extensive assay development and previous studies have shown that this is the minimum signal to noise threshold allowing maximum sensitivity without detecting large numbers of false positive responses. For proliferation data sets (n=3), positive responses were defined by statistical and empirical thresholds:
Significance (p<0.05) of the response by comparing cpm test wells against medium control wells using unpaired two sample student’s t-test.
Stimulation index greater than 2 (S1≥2), where S1=mean of test wells (cpm)/mean medium control wells (cpm).

In addition, intra-assay variation was assessed by calculating the coefficient of variance and standard deviation (SD) of the raw data from replicate cultures.

Results
The anti-TLR2 antibody OPN-305 (VK5/VH4) was purified to homogeneity by Protein A affinity chromatography followed by size exclusion chromatography. The variant named VK5/VH4 is the OPN-305 fully humanised monoclonal antibody disclosed herein. The OPN-305 monoclonal antibody is a fully humanised antibody having a light chain amino acid sequence defined herein as SEQ ID NO:2 and a heavy chain amino acid sequence defined herein in SEQ ID NO:5.

All preparations were derived from single peaks representing monomeric, non-aggregated antibody (FIGS. 15 A and B) and were found to contain endotoxin at ≤5 EU/mg.

The three test samples were tested against a cohort of 21 healthy donors using EpiScreen™ (Antitope, UK) time course T cell assays in order to determine the relative risk of immunogenicity. The samples were tested at a final concentration of 50 μg/ml as this amount provided a saturating concentration which was sufficient to stimulate detectable protein-specific T cell responses.

The results of the T cell modulation and cell toxicity studies were analysed. The cell viabilities in the cultures after seven days range from 65% to 95% and are similar between all test samples, media control and KLH control. The test samples were therefore not considered to have a toxic effect on the cells used in the assay. In addition, FIG. 16 shows that there are no significant differences (Student’s t-test p<0.05) between the S1s induced by KLH either alone or in the presence of the test samples. This suggests that the test samples do not directly modulate CD4+ T cell activation in response to KLH (control antigen). FIG. 16 shows the results of a pre-screen of test samples for cytotoxicity and T cell modulation activity. Sample 1 is chimeric anti-TLR2 (the Fab fragment derived from the T2.5 murine antibody conjugated to the Fc region of human IgG4), sample 2 is the anti-TLR2 antibody OPN-305 (VK5/VH4; OPN305), sample 3 is variant anti-TLR2 antibody designated VK5/VH5.

The results from the EpiScreen™ time course proliferation assay performed with the OPN-305 (VK5/VH4; OPN305) and VK5/VH5 comparative anti-Toll-like Receptor 2 antibodies as well as the anti-TLR2 chimeric antibodies were analysed (FIGS. 17 A, B and C). The chimeric anti-TLR2 antibody stimulated responses in 4 of the 21 donors (18% of the study cohort) where the S1s≥2 and significance was achieved in the Student’s t-test (p<0.05). However, no significantly different responses with high S1s throughout the test period and a strong response (S1=6.99) was also observed with donor 3 on day 6. In contrast none of the donors in the study cohort responded positively to OPN-305. The OPN-305 (VK5/VH4) antibody did not therefore produce any significant T cell responses in the donors that responded positively to the chimeric antibody.
Conclusions

The positive CD4+ T cell proliferation responses observed in the EpiScreen™ time course T cell assay against the chimeric antibody was in the expected range of 15-40%. Importantly, frequent and potent T cell responses were observed against the control antigen, KLH, that indicate that the assay functioned as expected. The results also show that the fully humanized antibody OPN-305 (VK5/V14) failed to induce any positive immune responses in any donors and this antibody is therefore considered to have a low risk of immunogenicity in the clinic.

FIG. 18 shows a clear correlation between the level of immunogenicity observed using the EpiScreen™ assay and the level of immunogenicity (anti-therapeutic antibody responses) that has been actually observed in the clinic against a large panel of therapeutic proteins (Baker and Jones, 2007). High levels of immunogenicity were observed in both the clinical data and EpiScreen™ assays for proteins such as Infliximab and Campath, whereas relatively low levels of immunogenicity were observed for proteins such as Xolair, Herceptin, and Avastin. Importantly, the OPN-305 antibody induced responses in <10% of the study cohort, which, based on previous experience is associated with biotherapeutics with a low risk of immunogenicity.

Example 8

Determination and Comparison of Binding Affinity of OPN-305 Monoclonal Antibody

Immunological biosensors, for example BIACORE™ surface plasmon resonance (SPR) instruments that measure the binding and dissociation of antigen-antibody complexes in real time, allow the elucidation of binding kinetics. The rate of dissociation of a compound and its subsequent optimisation is especially important for biopharmaceutical antibody development. BIACORE uses surface plasmon resonance (SPR) to monitor the interaction between a surface bound molecule ligand and its binding partner in solution ‘anlyte’, in real time. SPR is an electron charge-density wave phenomenon, which arises at the surface of a metallic layer when light is reflected at the layer under conditions of total internal reflectance. The surface plasmons that are generated are sensitive to any changes in the refractive index of the medium on the opposite side of the metallic layer from the reflected light. Protein-protein interactions occurring at the surface affect the refractive index of the medium and can therefore be detected. Binding of molecules to the ligand modified sensor surface generates a response, which is proportional to the bound mass allowing small changes in the amount of bound analyte to be detected (down to picogram levels). The technique can be used to measure affinity constants (KD) over the range 10^6-10^-12M, association rate constants (ka) between 103 and 107 M^-1 s^-1 and dissociation rate constants (kd) between 10^-2 and 10^-9 s^-1 (1-3).

The aim of this study was to use the BIACORE T100 surface plasmon (Biacore, Inc.) resonance instrument for the high resolution kinetic characterisation of the interaction between two related receptors and three mAbs. The two receptors under investigation were recombinant rhTLR-2 (recombinant human TLR-2) and rmTLR2/Fc (recombinant murine TLR-2).

Materials and Methods

Instrument Preparation

Before running any samples a system check (Biacore Preventative Maintenance Kit 2) was performed. All the systems tested passed (Reagent pump, Refractometer, Injections, Noise, Mixing and Buffer Selector) indicating that the instrument was performing to criteria set by the manufacturer. Following the system check the Desorb/Sanitize (Biacore Preventative Maintenance Kit 2) program was run to clean the instrument.

Assay Development

System Preparation

Upon insertion of the CM5 chip the system was primed and then normalised with BIAnormalising solution (Biacore Preventative Maintenance Kit 2). All samples were run at 25°C with a sample rack incubated at 25°C unless stated. The chip was added to the system with HBS-EP used as the running buffer. The chip surface was primed with two 30 second injections of 30 mM NaOH then left until a stable baseline was obtained in all the Flow cells (Fcs).

Sample Preparation

Two antibodies were analysed, the OPN-305 anti-Toll-like Receptor 2 antibody, as described herein, and the T2.5 murine anti-Toll-like Receptor 2 antibody (derived from hybridoma clone T2.5, HyCult Biotechnology b.v., Cell Sciences, Canton, USA: catalogue number 1054). Both monoclonal antibodies were stored as supplied and diluted to 1 μg/mL for all immobilization runs. The receptors rhTLR-2 and rmTLR2/Fc were reconstituted from the dry powder using HBS-EP to a final concentration of 1000 nM and stored at 4°C. No carrier protein was added to this solution.

Immobilisation Conditions and Activity

A direct assay was chosen for this study based on the results of a previous study where this set up was shown to be optimal. For kinetic experiments the amount of immobilised ligand needs to be limited to avoid mass transfer effects at the surface of the chip.

Using an average MW of 77.5 kDa for the glycosylated human receptor analyte (rhTLR-2), 150 kDa for the ligand (mAb) and the stoichiometry (Sm) as 2, an ideal target amount of ligand to immobilise would be 145 RU's. This level of immobilisation was also suitable for the murine receptor even though it had a MW of 98 kDa.

All antibodies were immobilised using standard amine coupling chemistry. Immobilisation was carried out at a protein concentration of around 1 μg.mL^-1 in 10 mM Acetate buffer pH5.5 to a target response level of 150 RU's on three CM5 Series S sensor chips. Kinetic data was obtained at a flow rate of 40 μl.min^-1 to minimise any potential mass transfer effects. The blank (no receptor) and a single concentration of the analytes (100 nM) was repeated at the start of the kinetic runs in order to check the stability of both the surface and two receptors over the kinetic analyses. Two repeats of the kinetic analysis were carried out and the results compared.

In order to observe a sufficient signal decrease (3-10%) during the dissociation phase of the kinetic cycles, dissociation was measured for 2000 seconds.

Results

The results are shown in Table 1. Association rates (K_a) and dissociation rates (K_d) were calculated using a bivalent binding model (Biacore Evaluation Software version 3.2). The equilibrium dissociation constant (K_D) was calculated as the ratio k_d/k_a.
The results indicate that OPN-305 binds to both human Toll-like Receptor 2 and murine Toll-like Receptor 2 with a higher binding affinity than the T2.5 monoclonal antibody. FIG. 19 shows an alignment showing the sequence identity between the amino acid sequences of the OPN-305 fully humanised anti-TLR2 antibody and the T.5 murine anti-TLR2 antibody. A sequence identity divergence of over 10% can be seen. Further, FIG. 20 shows an alignment of the heavy chain variable domain amino acid sequences of the OPN-305 fully humanised anti-TLR2 antibody and the T.5 murine anti-TLR2 antibody. Again, a sequence identity divergence of over 10% is present. Without wishing to be bound by theory, the inventor predicts that the variations in the amino acid sequence of the light and heavy chain of the OPN-305 antibody, over the T2.5 murine antibody, confer improved binding specificity and affinity to the OPN-305 antibody for Toll-like Receptor 2.

Example 9

Toll-like Receptor Occupancy Studies

This experiment was designed to identify the minimal occupancy levels required for inhibition of biological activity of the OPN-305 monoclonal antibody when binding to TLR2. Binding versus function was examined using a THP-1 reporter cell line. In particular the bioactivity of OPN-305 was assessed in Pam3CSK4 induced THP1-CD14 cells.

Materials and Methods

THP1-CD14 cells were seeded at a density of 1x10^6 cells per well in a 12 well plate. OPN-305 was added to the wells at various concentrations (ranging from 0.000488 mg/ml to 2 µg/ml) prior to the addition of Pam3CSK4 (200 ng/ml). Cells were incubated overnight at 37°C. NF-kB driven SEAP activity was measured by incubating the heat inactivated conditioned media with 160 µl of Quantiblue (Invivogen) reagent for 30 minutes at 37°C and absorbance was read at 650 nm.

To determine receptor occupancy of OPN305 in THP1-CD14 cells, the THP1-CD14 Blue cells were placed in FACS tubes (1x10^6/tube) and FcR were blocked with anti-CD32 blocking reagent (Milenyi Biotec) for 15 minutes. Cells were labelled with OPN-305 at the various concentrations (ranging from 0.000488 µg/ml to 2 µg/ml) for 15 minutes at room temperature. After washing, cells were incubated with RPE conjugated anti-human IgG4 for 15 minutes at room temperature. After a final wash step, cells were fixed with 2% formal saline in 1% BSA/PBS prior to acquisition. Percentage specific binding was calculated using the formula:

\[ \text{% specific binding} = \frac{MFI\text{ (OPN305}) - MFI\text{ (isotype}}} {\text{Max } MFI\text{(OPN305}) - MFI\text{ (isotype}}} \times 100 \]

Results

The results are shown in FIGS. 21A, B and C. These results show that inhibition of NF-kB activity is observed in a dose dependent manner following treatment with Pam3CSk4 (FIGS. 21A and B). OPN-305 almost completely inhibits NF-kB activity at concentrations of 2 µg/ml (FIG. 21C).

Percentage of specific binding of OPN-305 in THP1-CD14 cells was calculated using the formula described above.

Saturation binding experiments with THP-1 cells have been related back to inhibition of biological activity in the same populations of cells. Complete inhibition of TLR2 dependent signalling can be achieved with less than maximal receptor binding. This is a complex system and it seems likely that levels of TLR2 are significantly higher than in the heterodimeric partners TLR1 and TLR6. The receptor occupancy looks at saturation binding of TLR2 as a monomer or heterodimer. It seems likely that neutralisation of enough TLR2 to reduce probability of free TLR2 finding a partner to form a functional signalling complex may be an explanation for the apparent loss of biological activity at less than 100% receptor occupancy.

Example 10

Determination of Whether the OPN-305 Antibody Acts as a Competitive or Non-Competitive Inhibitor of TLR2 Dependent Signalling

Materials and Methods

THP1 CD14 Blue cells were seeded at 100,000 cells per well in a 96 well plate. Cells were briefly pre-incubated with 0, 1, 10 and 100 ng/ml of OPN-305 before being stimulated with varying doses of Pam3CSk4 overnight at 37°C. 40 µl of supernatant was removed and heat inactivated at 65°C for 10 minutes. NF-kB driven SEAP activity was measured by incubating the heat inactivated conditioned media with 160 µl of Quantiblue (Invivogen) reagent for 90 minutes at 37°C, followed by reading at 650 nm. Asymptotic receptor in the cell based assay behaves similarly to an enzyme, V (NF-kB activity) versus S [Pam3CSK4] was plotted as well as double reciprocal Lineweaver-Burk plots (1/V vs 1/S).

Results

The results are shown in FIG. 22, where FIG. 22A depicts NF-kB dependent SEAP activity versus [Pam3CSK4], while FIG. 22B depicts a Lineweaver Burk plot of 1/V versus 1/S. These results show that as ligand concentration is increased, a classic rightward shift of the dose response curve is seen (FIG. 22A). Analysis of the Lineweaver Burk plots (FIG. 22B) suggests a competitive mechanism at low ligand concentration but that the kinetics change as the ligand exceeds a certain threshold. Establishing the nature of the inhibitory effect is challenging in cells as the readout is biological activity and this is dependent not only on TLR2/ligand interaction but also the recruitment of TLR1 or TLR6 to generate a competent dimeric signalling complex. Expression profiling analysis using publicly available databases suggest that TLR2 is present in significant excess to TLR1 or TLR6 which may explain the potential for a bi-phasic response as an effect of titration of partner molecules.
Example 11

Determination of Whether OPN-305 Ligation to TLR2 Alters the Response to Other TLR2 Ligands

This experiment considered whether inhibition of TLR2 by OPN-305 affects the response of other TLRs to their respective ligands.

Materials and Methods

THP1 CD14 Blue cells were seeded at 25,000 cells per well in a 384 well plate. Cells were pre-incubated for 120 minutes with 0, 1, 10 and 100 ng/ml of OPN-305 or human IgG4 isotype control antibody before being stimulated with varying doses of different Toll-like Receptor ligand agonists. NF-kB driven SEAP activity was measured directly in the conditioned media following overnight incubation using HEP blue detection media.

Flagellin was used as a TLR5 ligand, ultra pure LPS as a TLR4 ligand and Pam3CSK and FSL-1 as TLR2 ligands.

Results

The results are shown in FIGS. 23A, B and C. Responses to flagellin (FIG. 23C) and LPS (FIG. 23B) were unaltered when compared to control cells not exposed to OPN-305. As expected Pam3CSK and FSL-1 mediated TLR2 activation responses were blocked by OPN-305 (FIG. 23A). Responses to flagellin and LPS were unaltered when compared to control cells not exposed to OPN-305. As expected Pam3CSK and FSL-1 responses were blocked by OPN-305. This suggests that OPN-305 is not bringing about any unexpected increase or decrease in TLR4 or TLR5 responsiveness to ligands.

Example 12

Use of OPN-305 in the Treatment of Sepsis

Materials and Methods:

Groups of female BALB/c mice (n=4) were treated with the OPN-305 monoclonal antibody at the doses of 10 mg/kg, 2 mg/kg and 0.4 mg/kg 30 minutes prior to treatment with 100 mg of Pam3CSK. All treatments were administered intraperitoneally. Four hours later, mice were sacrificed by lethal anaesthesia and blood was taken. Serum was derived and cytokine concentrations were determined by ELISA. Serum was diluted 1/10 for KC and IL-12p40 and 1/5 for IL-6 ELISAs.

Results:

The results are shown in FIGS. 24A, B and C. OPN305 is shown to inhibit Pam3CSK induced sepsis. Low dose (0.4 mg/kg) administration of the anti-TLR2 OPN305 can significantly inhibit Pam3CSK induced cytokines in mice.

This experiment was also repeated with OPN-305 only using i.v. (intravenous) administration of the OPN305 antibody followed by i.p. (intraperitoneal) injection of the TLR2 agonist Pam3CSK to ensure the positive effects were not a consequence of antibody and agonist being delivered to the same compartment.

The results of that experiment are shown in FIGS. 25A and B. The results show that the OPN-305 monoclonal antibody inhibits Pam3CSK induced sepsis. This result is equivalent to the previous experiment, demonstrating that OPN-305 delivered systemically can inhibit serum cytokine production in response to i.p. (intraperitoneal) administration of Pam3CSK.

Example 13

Binding of OPN-305 Monoclonal Antibody to TLR2 Expressed on Rat Cells

Materials and Methods

NR8383 cells were purchased from ATCC and grown in F12 media as instructed by ATCC. Cells were blocked with rat specific anti-CD32 (mouse IgG1) for 10 minutes at room temperature. Cells were treated with OPN305 (or isotype) for 15 minutes, washed, detected with RPE anti-human IgG4 and fixed with 2% formal saline prior to acquisition. NR8383 cells were also stained with a polyclonal rabbit anti-rat TLR2 antibody, and detected with Alexa-Fluor 488 anti-rabbit IgG.

Results:

The results are shown in FIG. 26 which shows that TLR2 expression is induced on rat alveolar macrophages (NR8383), and is detected using OPN305. (A) Unstained cells, (B) positive control; polyclonal rabbit anti-TLR2 primary antibody, secondary antibody was anti-rabbit Alexa-Fluor 488; (C) Cells treated with polyclonal human IgG4, secondary antibody was anti-IgG4 PE; (D) OPN305 stained cells, secondary antibody anti-human IgG4 PE.

Example 14

Binding of OPN-305 Monoclonal Antibody to TLR2 Expressed on Porcine Cells

Materials and Methods

Pig PBMCs were purified from blood using Ficoll. Cells were counted and 1x10⁶ cells were placed per tube. In the absence of a specific CD32 blocking reagent for pigs, cells were blocked using human anti-CD32 in a matrix of 50% FCS/BSA in PBS for 10 minutes. Cells were incubated with OPN305 (or isotype control) for 15 minutes at room temperature. 1H11 (mouse anti-pig TLR2, gift from Javier Dominguez) was used as a positive control. After washing, cells were incubated with RPE conjugated anti-human IgG4 for 15 minutes at room temperature. After a final wash step, cells were fixed, acquired and analysed.

Results

The results are shown in FIG. 27. TLR2 is expressed on porcine PBMCs and is stained by OPN305. PBMCs were purified by separation using Ficoll. A-C represents PBMCs from Pig 666 and D-F is from Pig 488. A, D is unstained; B, E is labelled with control polyclonal human IgG4, followed by secondary staining with PE labelled anti-human IgG4; C, F is labelled with OPN305, followed by PE labelled anti-human IgG4.

All documents referred to in this specification are herein incorporated by reference. Various modifications and variations to the described embodiments of the inventions will be apparent to those skilled in the art without departing from the scope of the invention. Although the invention has been described in connection with specific preferred embodiments, it should be understood that the invention as claimed should not be unduly limited to such specific embodiments. Indeed, various modifications of the described modes of carrying out the invention which are obvious to those skilled in the art are intended to be covered by the present invention.

The invention claimed is:
1. A neutralising antibody or an antigen binding portion thereof comprising a light chain variable domain comprising the amino acid sequence of SEQ ID NO: 1 or a sequence which has at least 90% amino acid sequence identity with SEQ ID NO: 1 and a heavy chain variable domain comprising the amino acid sequence of SEQ ID NO:4 or a sequence which has at least 90% amino acid sequence identity with SEQ ID NO:4, wherein the antibody or antigen binding portion specifically binds to Toll-like Receptor 2 (TLR2) and wherein the antibody or antigen binding portion antagonises TLR2 independently of binding of the antibody or antigen binding portion to CD32, and wherein the light chain variable domain comprises CDR1, CDR2 and CDR3 of SEQ ID NO:7, SEQ ID NO:8 and SEQ ID NO:9, respectively, and the heavy chain variable domain comprises CDR1, CDR2 and CDR3 of SEQ ID NO: 10, SEQ ID NO: 11 and SEQ ID NO: 12, respectively.
2. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the variable domain of the light chain is joined to a Kappa constant domain.
3. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the variable domain of the heavy chain is joined to at least one constant domain derived from an antibody of the subclass immunoglobulin G, isotype 4 (lgG4).
4. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 3 wherein amino acid residue 241 of a hinge region of the heavy chain is substituted from a serine residue to a proline residue (S241P).
5. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the light chain comprises the amino acid sequence of SEQ ID NO:2.
6. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 5 wherein the heavy chain comprises the amino acid sequence of SEQ ID NO:5.
7. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the heavy chain comprises the amino acid sequence of SEQ ID NO:5.
8. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the antibody is a fully humanised antibody or an antigen binding portion thereof.
9. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the antibody is an isolated antibody or an antigen binding portion thereof.
10. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the antibody or antigen binding portion binds to human Toll-like Receptor 2 with a $K_D$ of $3 \times 10^{-8}$ M or less.
11. An isolated nucleic acid molecule encoding the antibody or antigen binding portion thereof of claim 1.
12. An expression vector comprising the nucleic acid molecule of claim 11.
13. An isolated host cell comprising the expression vector of claim 12.
14. A method of producing a neutralising Toll-like Receptor 2 antibody or antigen binding portion thereof comprising culturing the host cell of claim 13 under appropriate conditions such that the antibody or antigen binding portion thereof
is expressed and isolating the antibody or antigen binding portion thereof from the host cell or from cell culture supernatant.

15. A hybridoma cell line producing the antibody or antigen binding portion as claimed in claim 1.

16. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the antibody or antigen binding portion has binding specificity to human Toll-like Receptor 2, mouse Toll-like Receptor 2 and monkey Toll-like Receptor 2.

17. The Toll-like Receptor 2 neutralising antibody or antigen binding portion as claimed in claim 1 wherein the light chain variable domain has the amino acid sequence of SEQ ID NO:1 and the heavy chain variable domain has the amino acid sequence of SEQ ID NO:4.

18. The neutralising antibody or antigen binding portion thereof as claimed in claim 1 wherein the light chain variable domain has the amino acid sequence of SEQ ID NO:1 or a sequence which has at least 95% amino acid sequence identity with SEQ ID NO:1 and the heavy chain variable domain has the amino acid sequence of SEQ ID NO:4 or a sequence which has at least 95% amino acid sequence identity with SEQ ID NO:4.

19. A method for treating an inflammatory, respiratory or autoimmune condition or disease which is mediated by Toll-like Receptor 2 activation, comprising administering in-vivo or ex-vivo, a therapeutically effective amount of the antibody or an antigen binding portion thereof according to claim 1 to a subject in need of such treatment.

20. The method as claimed in claim 19 wherein the inflammatory, respiratory or autoimmune condition or disease is selected from the group consisting of rheumatoid arthritis, asthma, chronic obstructive pulmonary disease, allergic response, psoriasis, dermatitis, multiple sclerosis, atherosclerosis, ischemia reperfusion injury, ischemia reperfusion resulting from organ transplantation, ocular disease, uveitis, age-related macular degeneration, renal inflammation and diabetes.

21. A method for treating or preventing sepsis, comprising administering a therapeutically effective amount of the antibody or antigen binding portion according to claim 1 to a subject in need of such treatment.

22. An isolated monoclonal antibody, or antigen binding portion thereof, which binds an epitope on human Toll-like Receptor 2 with a $K_d$ of $3 \times 10^{-8}$ M or less and which mediates Toll-like Receptor 2 antagonism independently of binding of the antibody or antigen binding portion to CD32 (Fc gamma receptor II), wherein the epitope is recognised by a reference antibody, wherein the reference antibody comprises a heavy chain variable region comprising the amino acid sequence of SEQ ID NO:4 and a light chain variable region comprising the amino acid sequence of SEQ ID NO:1.

23. The isolated monoclonal antibody or antigen binding portion thereof as claimed in claim 22 wherein the reference antibody comprises the heavy chain of SEQ ID NO:5 and the light chain of SEQ ID NO:2.

24. The isolated monoclonal antibody; or antigen binding portion thereof as claimed in claim 22 wherein the antibody or antigen binding portion has binding specificity to human Toll-like Receptor 2, mouse Toll-like Receptor 2 and monkey Toll-like Receptor 2.
